Rosuvastatin vs. Atorvastatin Treatment in LODESTAR Trial

Randomized comparison of rosuvastatin vs. atorvastatin treatment in patients with coronary artery disease: a secondary analysis of the randomized LODESTAR trial

Myeong-Ki Hong

on behalf of the LODESTAR trial investigators

Severance Hospital and Yonsei University College of Medicine, Seoul, Korea

Background

- **Statins in coronary artery disease**
  - Intensive lowering of low-density lipoprotein (LDL) cholesterol levels is recommended in patients with coronary artery disease (CAD).
  - Among the various lipid-lowering drugs, statins are the cornerstone of therapy and high-intensity statins are generally used as the first-line therapy in patients with CAD.
  - Physicians make decisions for not only statin intensity but also statin type.

Mach F, et al. Eur Heart J 2020;41:111-188
Grundy SM, et al. J Am Coll Cardiol 2019;73:e285-350

  - However, few RCTs have directly compared the long-term clinical outcomes of the two most potent statins (rosuvastatin versus atorvastatin) in patients with CAD.

- **Aims**
  - To compare the long-term efficacy and safety between the rosuvastatin and atorvastatin treatment in patients with CAD

Study design

- LODESTAR :A randomised, open-label, multicenter trial (Hong SJ, et al. JAMA 2023;329:1078-1087)
- 2-by-2 factorial randomization (statin type and statin intensity strategy)
- Enrollment period: September 9, 2016 and November 27, 2019

- Key inclusion criteria
  - Patients ≥19 years old
  - Patients clinically diagnosed with coronary artery disease: stable angina, unstable angina, acute non-ST elevation myocardial infarction, and acute ST elevation myocardial infarction
  - Patients with signed informed consent

- Key exclusion criteria
  - Pregnant women or women with potential childbearing during the study period
  - Patients with severe adverse events or hypersensitive to statin
  - Patients receiving drug that interacts with statin (strong inhibitor of cytochrome p-450 3A4 or 2C9)
  - Patients with risk factors for myopathy, hereditary muscle disorder, hypothyroidism, alcohol use disorder, severe hepatic dysfunction (3 times the normal reference values), or rhabdomyolysis
  - Life expectancy <3 years
  - Patients who could not be followed for more than 1 year
  - Patients who could not understand the consent form

Study design

Patients with Coronary Artery Disease
N=4400

1:1 Randomization

Rosuvastatin treatment	**Atorvastatin treatment**
N=2204	**N=2196**

Clinical follow-up at 3 years
Composite of all-cause death, myocardial infarction, stroke, or any coronary revascularization

Trial Registration: Clinicaltrial.gov Identifier: NCT02579499

Statistical analysis

- The sample size estimation for the LODESTAR trial was performed on the basis of determining the primary objective of the study: to compare the treat-to-target strategy (target LDL cholesterol, 50-70mg/dL) with the high-intensity statin strategy in terms of 3-year occurrence of the primary outcome.

  Hong SJ, et al. *JAMA* 2023;329:1078-1087

- A 2-by-2 factorial randomization was prespecified, nevertheless, the sample size estimation was not performed for comparing the randomized statin types.

- Interaction between statin type and statin intensity strategy regarding the primary outcome was estimated, and there was no significant interaction.

- **This study focused on the randomized statin types in the LODESTAR trial**
  → 3-year clinical outcomes between the rosuvastatin and atorvastatin treatment in patients with CAD were evaluated

Study flow

4400 underwent randomization

2204 Were assigned to receive rosuvastatin	**2196 Were assigned to receive atorvastatin**
1935 Received rosuvastatin as randomized	1898 Received atorvastatin as randomized

Conclusion

- To our knowledge, this study is the first randomised trial comparing 3-year clinical outcomes of rosuvastatin treatment versus atorvastatin treatment in patients with CAD.

- The 3-year composite of all-cause death, MI, stroke, or any coronary revascularization did not differ between the rosuvastatin and atorvastatin treatment.

- Rosuvastatin treatment was associated with lower LDL cholesterol levels, but it also carried a higher risk of new-onset diabetes mellitus requiring anti-diabetic medication and cataract operation, compared with atorvastatin treatment.

Background

- In 2021, 529 million individuals were living with diabetes (DM) globally
- Diabetes doubles the risk of atherosclerotic cardiovascular disease
- LDL-C lowering with statins as first-line treatment reduces this risk in patients with DM (CARDS trial)
- Secondary prevention patients with DM derive greater absolute benefits when non-statin LLTs, such as ezetimibe and PCSK9 mAbs, are added to statins
- Many patients are unable to tolerate or maximize a statin leaving them at high residual risk of CVD

Background (cont)

- **Statins increase the risk of new-onset diabetes (NOD) in a dose dependent fashion**
  - Genetics suggest an on-target effect of HMGCoA inhibition
- **In trials with ezetimibe or PCSK9i added to statins there was no excess risk of NOD**
  - Genetics suggest that lower NPC1L1 or PCSK9 activity would increase risk of NOD
- **Genetic studies suggested that lower activity of ACLY, the target of Bempedoic Acid, would reduce CVD with no excess risk of NOD**

CLEAR Outcomes

Patients with, or at high risk for, CVD who are unable or unwilling to take guideline-recommended doses of statins

VISIT T1 (Day 1) (N=13970)

R

1:1

Bempedoic Acid 180 mg QD

End of Study Criteria

1. At least 1,620 adjudicated primary MACE-4
2. At least 810 adjudicated MACE-3
3. At least 24 months since the last patient was randomized

Placebo

Median Follow-Up: 40.6 months

Enrollment: December 2016 – August 2019

Time to Event Outcomes	Bempedoic Acid (N=6992)	Placebo (N=6978)	Bempedoic Acid vs Placebo	
	Events (n), %		HR (95% CI)	*P*-value
MACE-4	819 (11.7)	927 (13.3)	0.87 (0.79-0.96)	0.004
MACE-3	575 (8.2)	663 (9.5)	0.85 (0.76-0.96)	0.006

Prespecified DM Analysis - Endpoints

Efficacy Outcomes

- **MACE-4:** Cardiovascular death, non-fatal MI, non-fatal stroke, or coronary revascularization
- **MACE-3:** Cardiovascular death, non-fatal MI, or non-fatal stroke

Clinical Outcomes

- HbA1c*
- Fasting Glucose*
- New Onset Diabetes

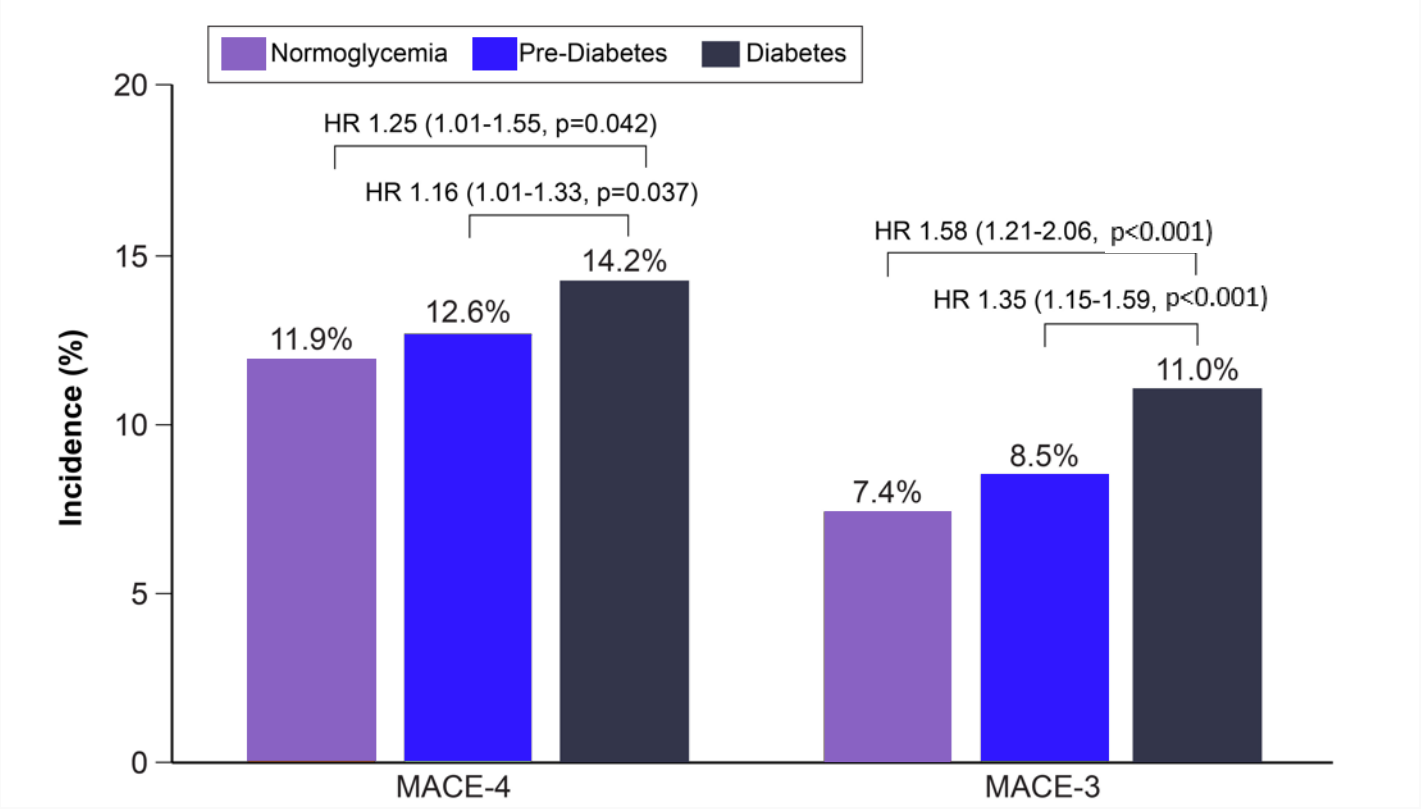
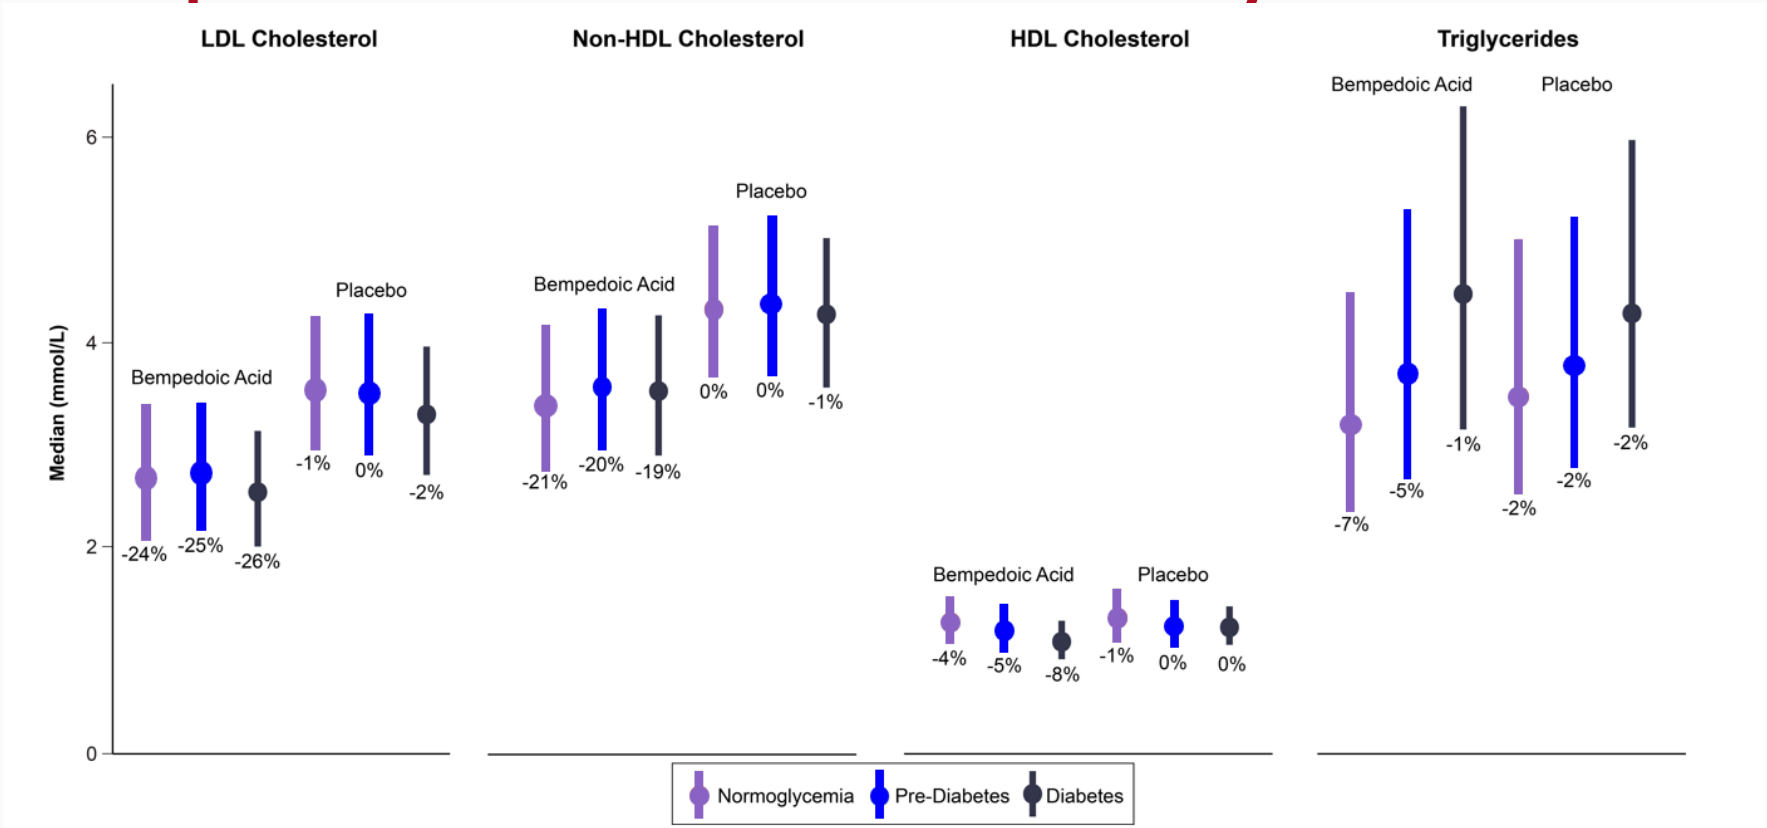
Incidence of Cardiovascular Events in the Placebo Group Increased Across Glycaemic Strata



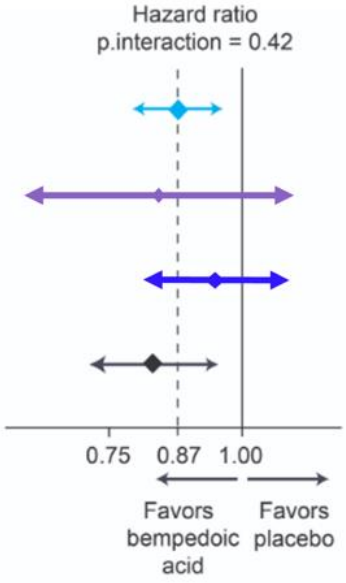
At 6 months LDL-C and non-HDL-C reductions with Bempedoic Acid were similar across Glycaemia Strata

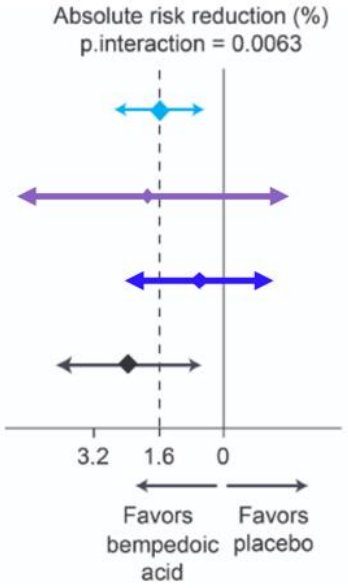


Error bars are IQRs. Median within-patient percentage changes from baseline are shown below each data point.

Bempedoic Acid provided similar relative but greater absolute benefits on MACE-4 in those with DM

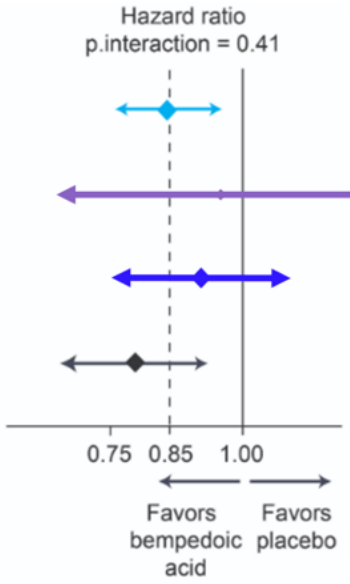
	Bempedoic Acid n/N (%)	Placebo n/N (%)	Hazard ratio (95% CI)	Absolute Reduction (95% CI)
Overall	819/6992 (11.7%)	927/6978 (13.3%)	0.87 (0.79, 0.96)	1.6% (0.5%, 2.7%)
Normoglycemia	95/937 (10.1%)	103/864 (11.9%)	0.84 (0.63, 1.10)	1.9% (-1.12%, 4.8%)
Pre-Diabetes	350/2911 (12.0%)	364/2885 (12.6%)	0.94 (0.81, 1.09)	0.6% (-1.1%, 2.3%)
Diabetes	374/3144 (11.9%)	460/3229 (14.2%)	0.83 (0.72, 0.95)	2.4% (0.7%, 4.0%)

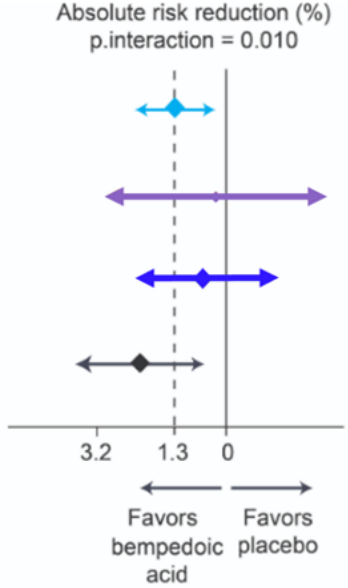




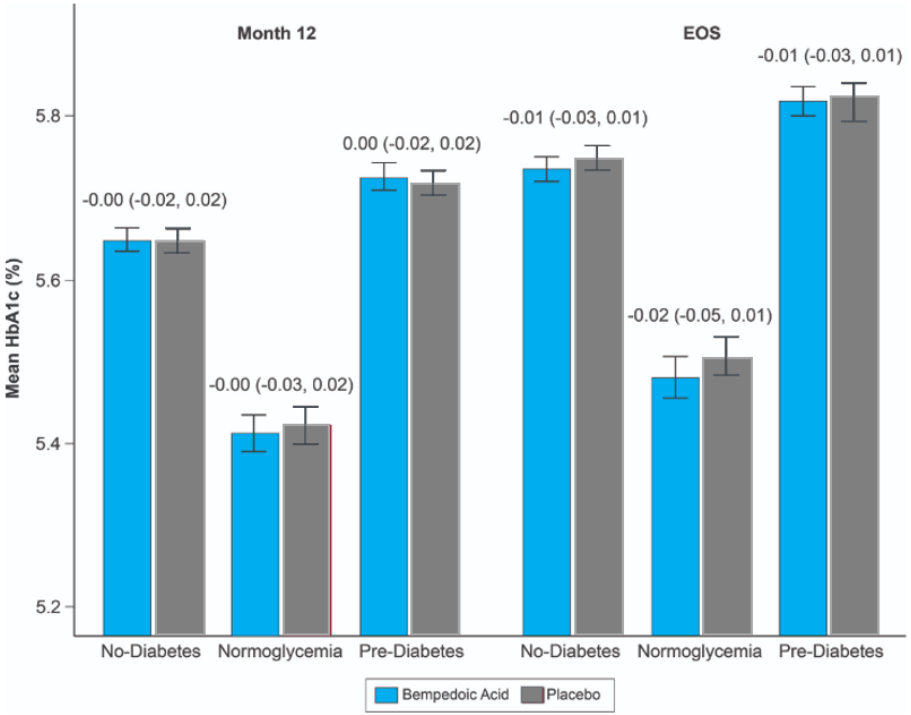
Bempedoic Acid provided similar relative but greater absolute benefits on MACE-3 in those with DM

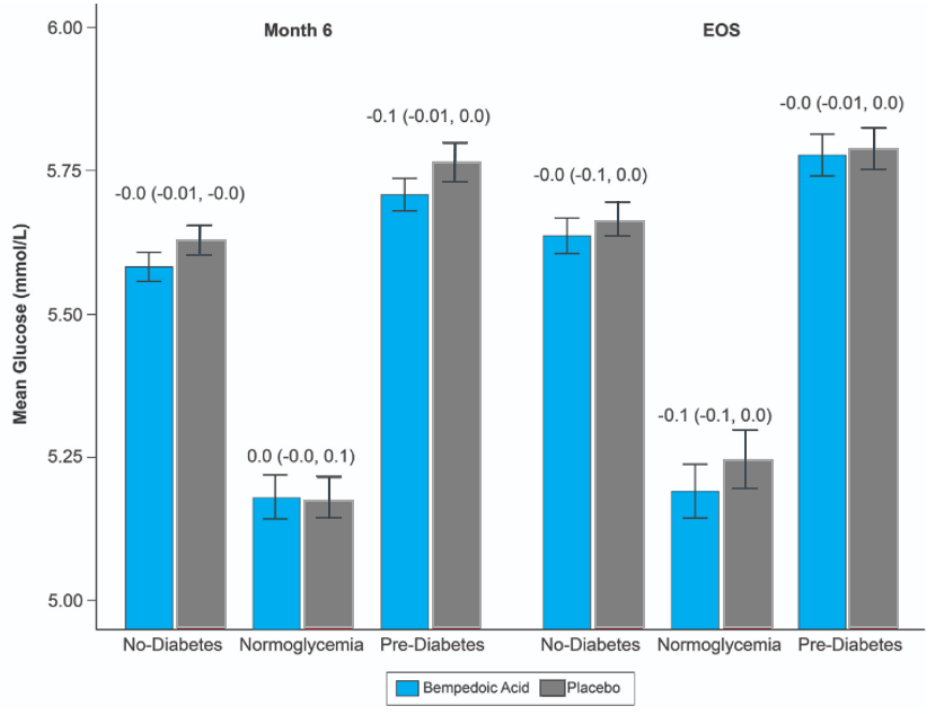
	Bempedoic Acid n/N (%)	Placebo n/N (%)	Hazard ratio (95% CI)	Absolute Reduction (95% CI)
Overall	575/6992 (8.2%)	663/978 (9.5%)	0.85 (0.76, 0.96)	1.3% (0.3%, 2.2%)
Normoglycemia	67/937 (7.2%)	64/864 (7.4%)	0.96 (0.68, 1.35)	0.3% (-2.1%, 2.7%)
Pre-Diabetes	229/2911 (7.9%)	244/2885 (8.5%)	0.92 (0.77, 1.10)	0.6% (-0.8%, 2.0%)
Diabetes	279/3144 (8.9%)	355/3229 (11.0%)	0.80 (0.68, 0.93)	2.1% (0.7%, 3.6%)





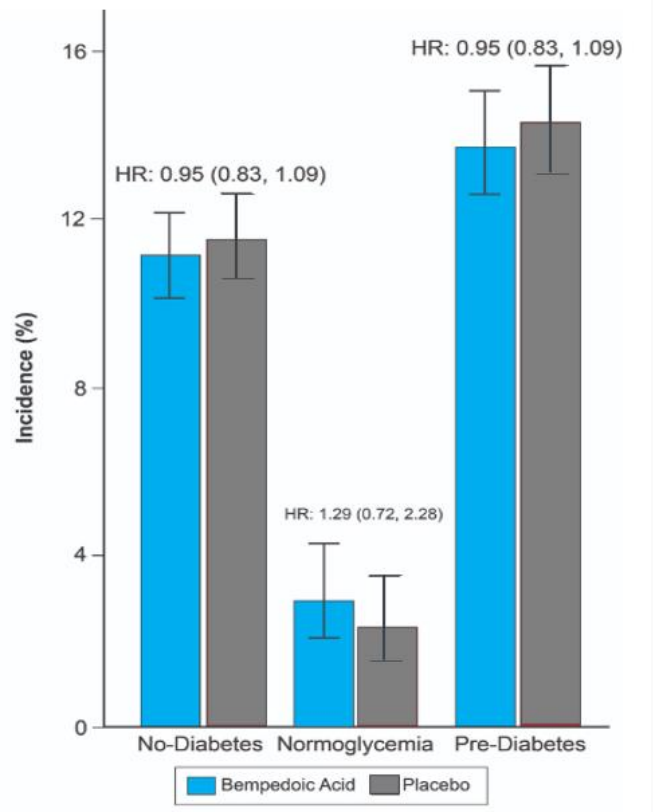
Bempedoic Acid did not worsen HbA1c or glucose levels in those without diabetes



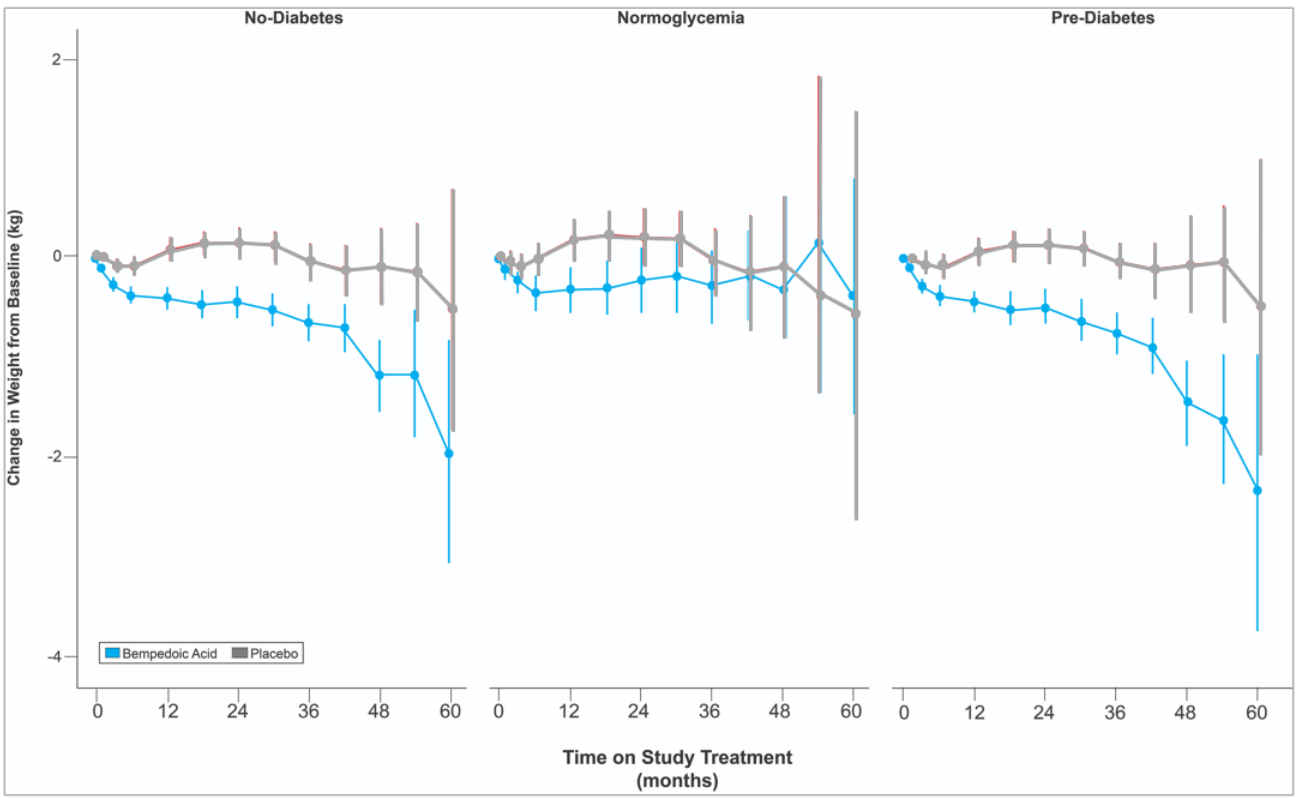


Bempedoic Acid did not increase the risk of New Onset Diabetes

- Individuals with normoglycaemia or prediabetes at baseline were considered to have NOD during the trial if one or more of the following criteria were met as defined in the ADA guidelines:
  - HbA_{1c} value of 6·5% or higher; or
  - Fasting serum glucose value of at least 7·0 mmol/L; or,
  - Two-hour post prandial glucose ≥11·1 mmol/L during an oral glucose tolerance test; or,
  - In a patient with classic symptoms of hyperglycaemia or hyperglycaemic crisis, a random plasma glucose ≥ 11·1 mmol/L, or initiation of glucose lowering therapies.
  - In the absence of unequivocal hyperglycaemia, diagnosis required two abnormal test results from the same sample or in two separate test results.



Weight was lower in Bempedoic Acid treated patients compared to Placebo



Concordance of Mendelian Randomization and Pharmacotherapy RCTs

	Enhancing LDL Receptor Activity							
Pathway	**Cholesterol synthesis pathway**				**Cholesterol absorption**		**LDL receptor degradation**	
Target	**ACLY**		**HMGCoA**		**NPC1L-1**		**PCSK9**	
Mechanism of lowering	***Genetically Lower***	***Bempedoic Acid***	***Genetically lower***	***Statins***	***Genetically lower***	***Ezetimibe***	***Genetically lower***	***PCSK9i MAbs***
Efficacy								
LDL-C	Lower	Lower	Lower	Lower	Lower	Lower	Lower	Lower
CVD	Lower	Lower	Lower	Lower	Lower	Lower	Lower	Lower
Safety								
Weight or BMI	Lower	Lower	Higher	Higher	Unknown	Unknown	Unknown	Unknown
HbA1c/glucose	Neutral	Neutral	Higher	Higher	Higher	Neutral	Higher	Neutral
New Onset Diabetes	Neutral	Neutral	Higher	Higher	Higher	Neutral	Higher	Neutral

ACLY = ATP-citrate lyase; HMGCoA = 3-hydroxy-3-methylglutaryl coenzyme-A; NPC1L-1 = Niemann–Pick C1-like 1; PCSK9 = proprotein convertase subtilisin/kexin type 9; LDL = low density lipoprotein; LDL-C = low density lipoprotein cholesterol; CVD = cardiovascular disease; BMI = body mass index

Conclusion

- In patients with DM unwilling or unable to take guideline-recommended doses of statins, Bempedoic Acid significantly reduced cardiovascular risk with large absolute benefits as monotherapy
- In patients without DM at baseline, there were no adverse effects of Bempedoic Acid on measures of glycaemia or risk of New Onset Diabetes
- These data validate prior genetic data for ACLY inhibition for reducing LDL-C and risk of CV disease with no adverse effect on measures of glycaemia

RED-CVD trial

#ESCCongress

Improving early diagnosis of CVD in patients with type 2 diabetes and COPD

Conclusion

Active screening of patients with type 2 diabetes or chronic obstructive pulmonary disease (COPD) more than doubles new diagnoses of CVD compared with usual care.

Impact on clinical practice

A proactive diagnostic strategy identifies coronary artery disease (CAD), atrial fibrillation (AF) and heart failure (HF) in the community.

Study objectives

RED-CVD was a cluster randomised, pragmatic trial examining the ability of a stepwise diagnostic strategy to identify CAD, AF and HF in patients with COPD or type 2 diabetes using tools readily available in primary care.

Study population

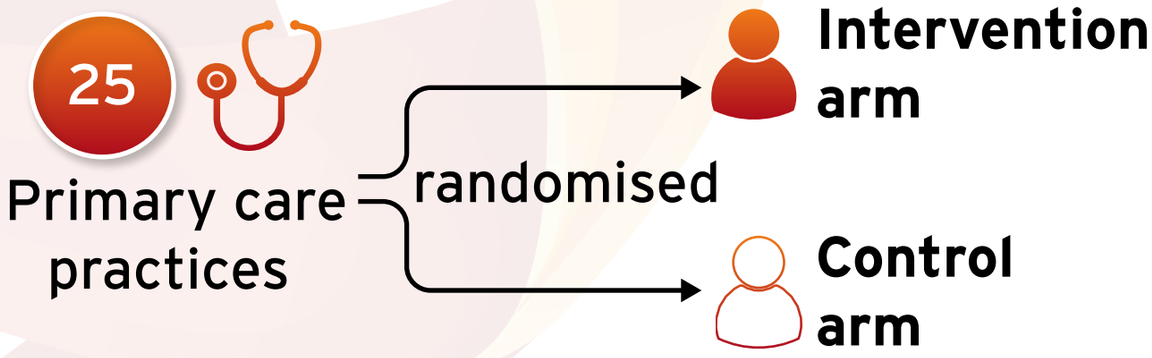
Primary care practices were the unit of randomisation.

Primary care practices across the Netherlands were eligible if they could add the early diagnosis strategy to their usual disease management programmes for type 2 diabetes and COPD.

Where?

the Netherlands

Who and what?



The intervention had 3 steps

Questionnaire on risk factors and symptoms, to be filled out at home prior to the next routine visit to a type 2 diabetes or COPD management programme;

For patients who scored above a prespecified threshold on the questionnaire: physical examination by the practice nurse focused on signs of HF, 12-lead electrocardiography and NT-proBNP measurements, to be performed during a routine visit;

Interpretation of the results of steps 1 and 2 by a GP and referral to a cardiologist or open access echocardiography if deemed necessary.

Primary endpoint

Composite of newly detected cases of HF, AF and CAD at 1 year after the baseline visit.

50 of 624 participants — 8.0%

19 of 592 participants — 3.2%

- Newly diagnosed with at least one of HF, AF or CAD
- Adjusted odds ratio 2.83; 95% CI 1.62 to 4.95

Screening for heart failure and optimising pathways of care in people with pacemakers: The OPT-PACE randomised controlled trial

Klaus Witte

Leeds Institute of Cardiovascular and Metabolic Medicine,
University of Leeds, GB

k.k.witte@leeds.ac.uk @KlausKWitte

NIHR | National Institute for Health Research

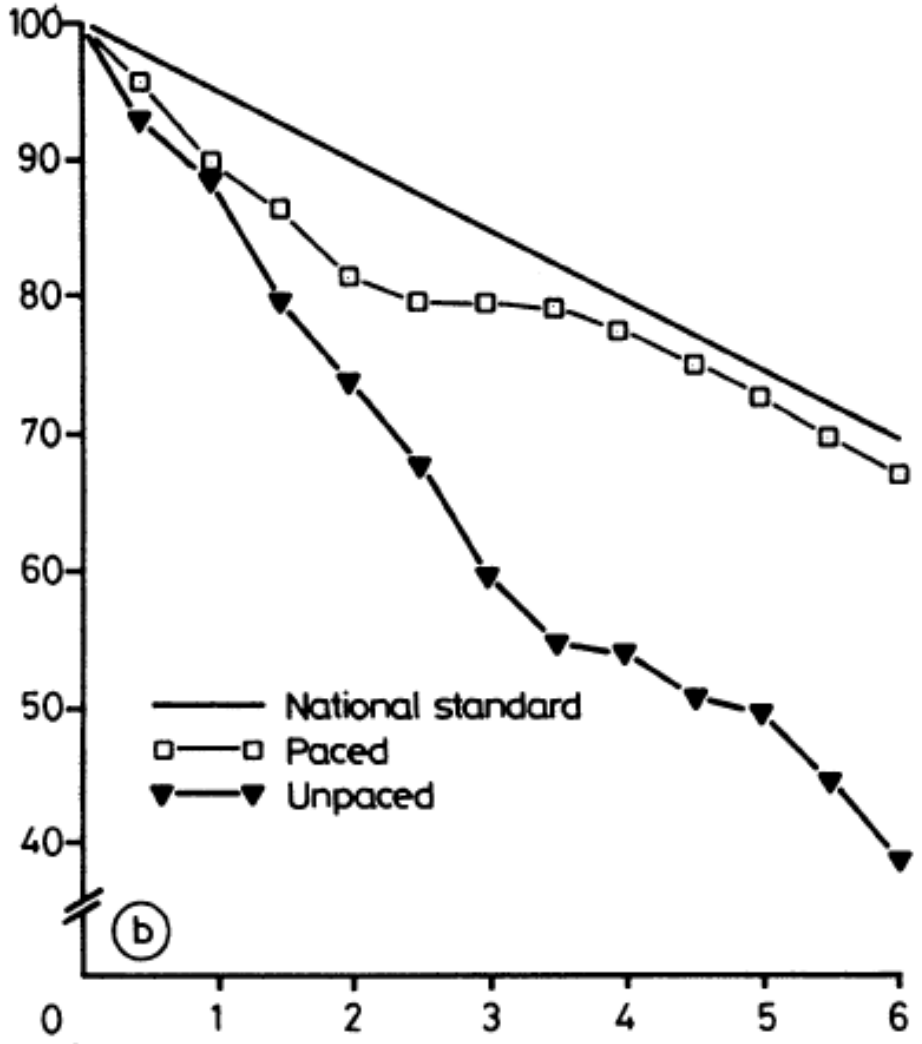
Disclosures

OPT-PACE was an independent investigator-initiated trial, funded through an NIHR Clinician Scientist Award to Klaus Witte (NIHR-CS-2012-032)

Background: Pacemakers for bradycardia

UNIVERSITY OF LEEDS

- ~1 million pacemaker implants per year worldwide
- Rates vary widely across Europe (median is ~600 per million per year)
- 80% are implanted in people >65 years of age
- Pacemaker therapy for AV block extends life
- But it comes at a cost…



Timmis *et al*. *Eur Heart J* 2018
Mond *et al*. *PACE* 2011
Shaw *et al*. *Br Heart J* 1985

Complication: Heart Failure

Medical therapy for pacing-associated HF

UNIVERSITY OF LEEDS

Check the guidelines

OPT-PACE: Aim

UNIVERSITY OF LEEDS

To determine the benefit of screening for heart failure *and* optimising medical therapy in people with pacemakers

OPT-PACE: Trial design

UNIVERSITY OF LEEDS

- Prospective, multicenter, randomised, controlled
- Academic trial without industry involvement
- Funding: National Institute for Health Research (UK) (NIHR-CS-2012-032)
- Sponsor: University of Leeds (Leeds Institute for Cardiovascular and Metabolic Medicine)
- Statistical management: Leeds Institute for Clinical Trials Research
- Participating centres:

  Leeds teaching Hospitals NHS Trust,

  Bradford Hospitals NHS Trust,

  Harrogate District Hospital NHS Trust
- Ethical approval: Health Research Authority (South Yorkshire Research Ethics Committee: 12/YH/0487)
- Clinical Trials registration: ClinicalTrials.gov (NCT01819662)

OPT-PACE: Participants

UNIVERSITY OF LEEDS

Inclusion criteria:

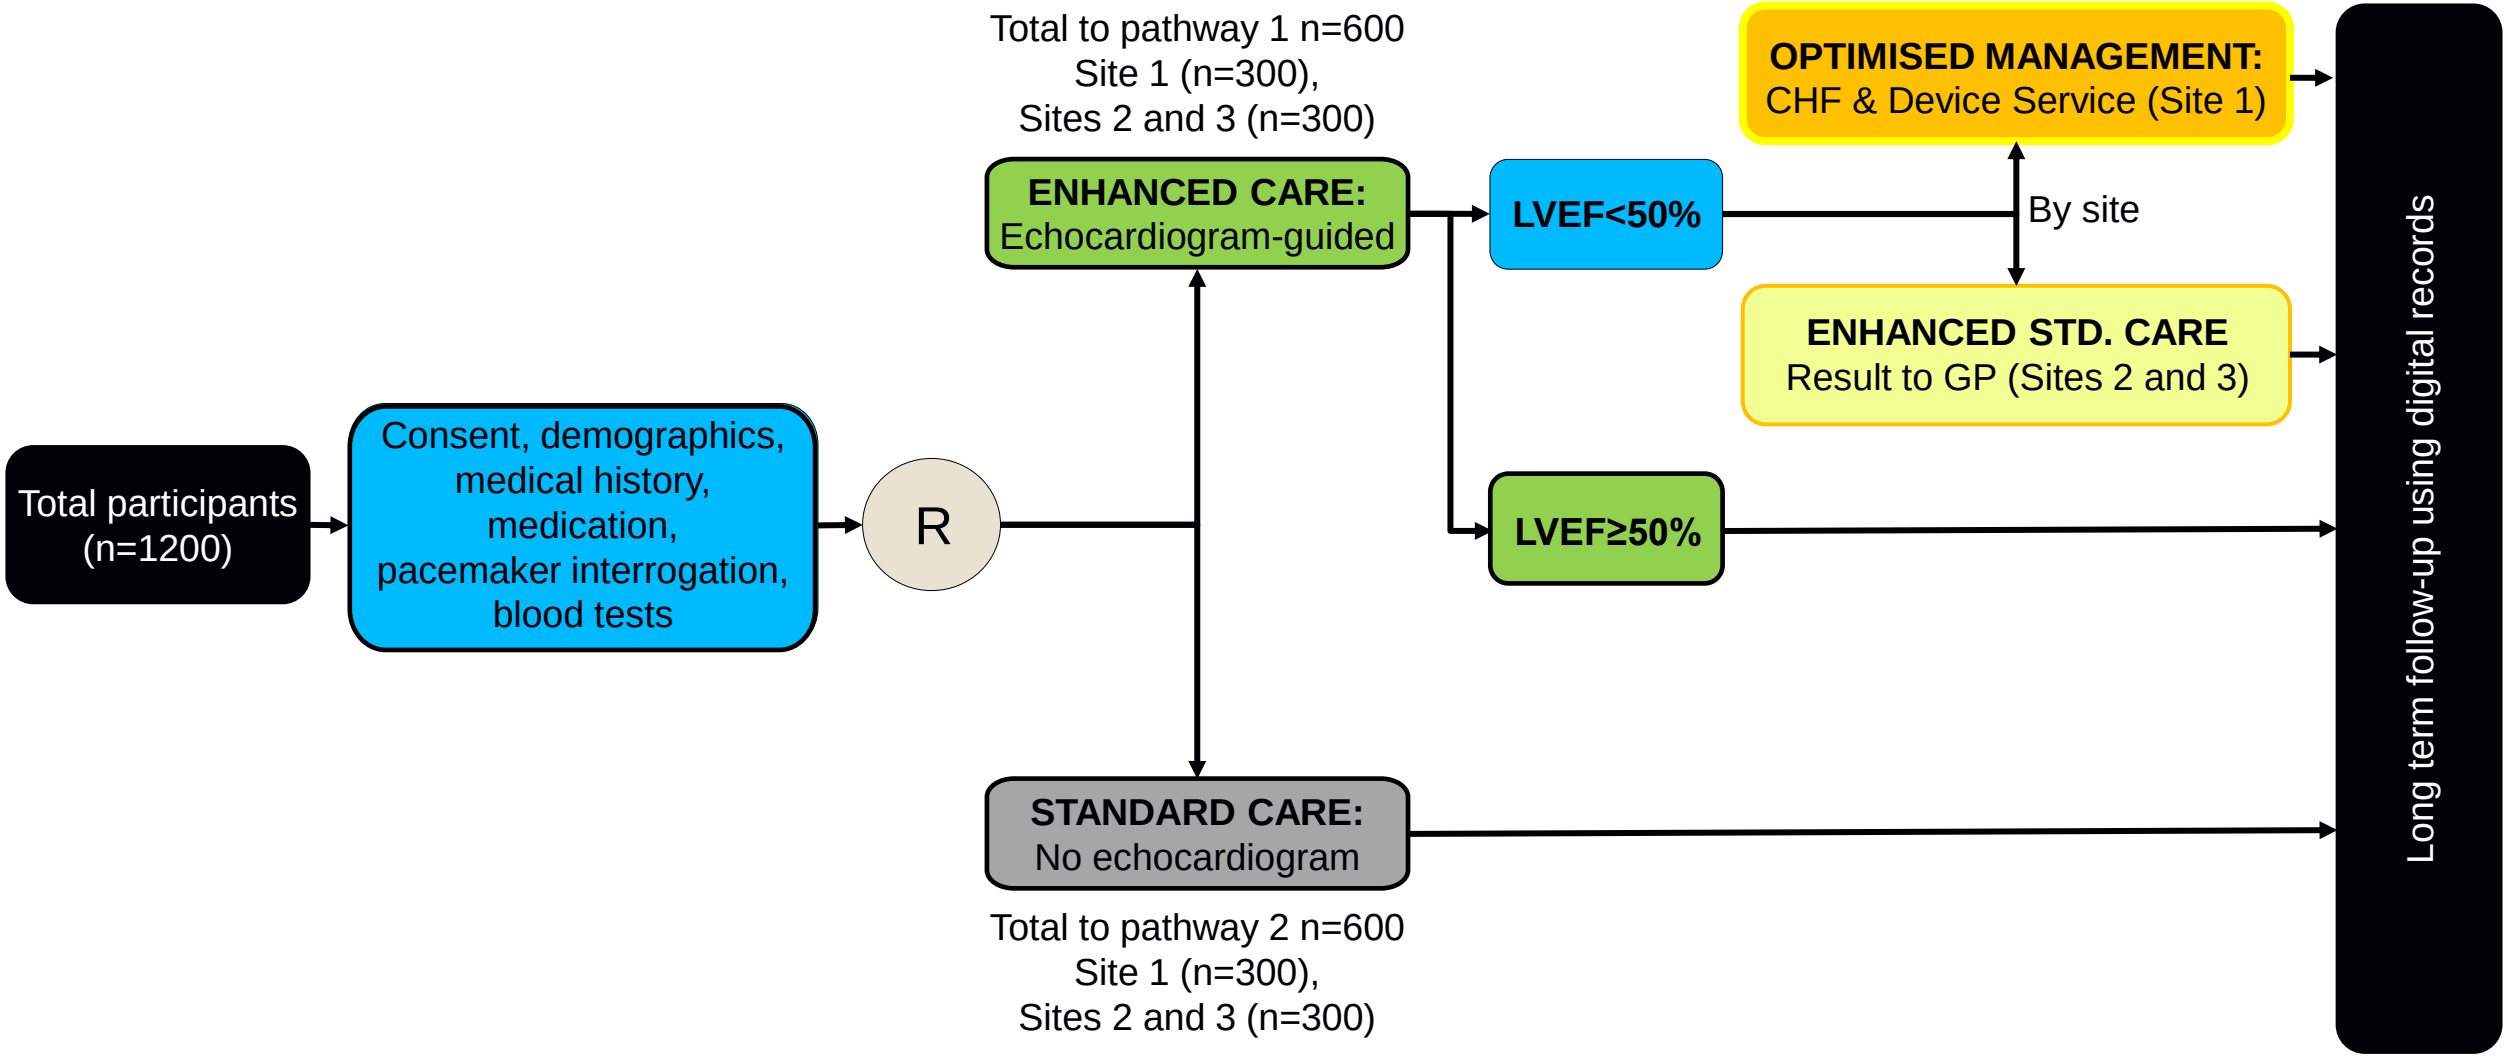
- Standard pacemaker implanted for bradycardia for >12 months due to any indication in current clinical ESC guidelines.

Exclusion criteria:

- Existing implantable cardioverter defibrillator or cardiac resynchronisation device;
- <18 years old;
- Pregnant;
- Known HFrEF;
- Already under the care of HF services, awaiting heart transplantation;
- Life expectancy of <1 year due to co-morbidity;
- Significant cognitive impairment.

OPT-PACE: Pathways of care

UNIVERSITY OF LEEDS



OPT-PACE: Endpoints

UNIVERSITY OF LEEDS

Primary:
Time to first event of all-cause mortality or heart failure hospitalisation between randomised groups (echocardiogram *versus* no echocardiogram).

Prespecified subgroup analysis of pathways of care in the echocardiogram group (primary care driven management versus chronic heart failure and device service)

Secondary:
Effect on medical therapy of optimised management of a population with a pacemaker

Effect of medical therapy on quality of life

OPT-PACE: Statistical considerations

UNIVERSITY OF LEEDS

Background Data: 491 patients, 40% prevalence of CHF, but **15% p.a. hosp for HF/death**

Primary endpoint: Effect of enhanced investigation and optimised management on total mortality, HFH

Power calculation: 15% HFH/death rate reduced to 9% by CHAD Service based upon reduction of event rates with combined optimal medical therapy and a power of 0.90 with overall two-sided type 1 error rate 0.05) required 146 events in 1020 participants in each group (uplifted to 1200 to account for ~10% drop-out

Recruitment target: 200 patients with LVSD

Randomised: Echocardiogram pathway and then treatment allocated by centre

OPT-PACE: Flow diagram of inclusions

UNIVERSITY OF LEEDS

Continuous variables are expressed as mean (95% Confidence Interval)

ACEi; Angiotensin-converting-enzyme inhibitor,
ARB; Angiotensin II receptor blocker,
MRA; mineralocorticoid receptor antagonist.

OPT-PACE: Limitations

UNIVERSITY OF LEEDS

- Trial recruited in three hospitals in Yorkshire in the UK
  - (2 secondary care and 1 teaching hospital);
- No SGLT2i (likely to contribute to greater effect in the ‘intervention’ arm);
- Excluded people with known LVSD (likely to contribute to greater effect in the ‘intervention’ arm);
- Regionally held digital data for hospitalisation endpoints (unlikely hospitalisation elsewhere, and likely balanced across groups) – national data for mortality updated daily;
- Delay to the effects of optimal medical therapy;
- OPT-pace was study of medical optimisation, and not of the benefits of CRT upgrade.

OPT-PACE: Conclusions

UNIVERSITY OF LEEDS

Screening for LV dysfunction in patients with pacemakers will identify a large proportion of people with HFrEF

Screening and identification alone does not lead to improved outcomes

Optimal therapy for these patients associated with lower hospitalisation and mortality rates

Medical optimisation in patients with HF and a pacemaker should be delivered in a combined CHF&Devices clinic

Future outcomes studies of device for bradycardia need to include optimal medical therapy in both groups.

‘It’s not just about the data, it’s also how you use them’

BUDAPEST CRT Upgrade trial

#ESCCongress

CRT upgrade in HF with RV pacing

Conclusion

Upgrade to cardiac resynchronisation therapy with a defibrillator (CRT-D) reduces morbidity and mortality and improves left ventricular reverse remodelling in select patients with heart failure and reduced ejection fraction (HFrEF) and intermittent or permanent right ventricular (RV) pacing.

Impact on clinical practice

HFrEF patients with a pacemaker or ICD should be strictly followed in clinical practice and in those with intermittent or permanent RV pacing, a CRT upgrade should be performed immediately without deferring the procedure to a later date (e.g. battery replacement).

Study objectives

BUDAPEST CRT Upgrade was the first trial to compare the efficacy and safety of a CRT upgrade, compared to ICD alone, in HFrEF patients with a pacemaker or ICD and intermittent or permanent RV pacing.

Study population

HFrEF patients

- with ejection fraction ≤35%
- had received a pacemaker or ICD >6 months previously
- had HF symptoms
- had a wide paced QRS complex
- had a high burden of RV pacing
- treated with guideline-directed medical therapy

Patients were excluded if they were eligible for CRT according to current guidelines

NOAH-AFNET 6 trial #ESCCongress

Oral anticoagulation in patients with atrial high-rate episodes

Conclusion

Blood thinners (anticoagulants) cause bleeding without preventing stroke in patients with atrial high-rate episodes (AHRE), but without electrocardiogram (ECG)-diagnosed atrial fibrillation.

Impact on clinical practice

The results clearly suggest to demand ECG documentation of atrial fibrillation prior to initiation of oral anticoagulation.

Study objectives

NOAH-AFNET 6 was the first trial to investigate the efficacy and safety of oral anticoagulation in patients with AHRE, but without ECG-documented atrial fibrillation.

Study population

Patients ≥65 years with

- AHRE episodes ≥6 minutes detected by implantable devices
- ≥1 additional stroke risk factor
  - heart failure
  - hypertension
  - diabetes
  - prior stroke or transient ischaemic attack
  - vascular disease
  - age ≥75 years

PW CL according to PW voltage status. There was no significant difference between those with or without low voltage with respect to average PW cycle length (left) or fastest PW cycle length (right).

Conclusions

- Rapid posterior wall activity is associated with an ↑risk of AF recurrence post catheter ablation.
- The addition of PWI in this subgroup was associated with a significant improvement in freedom from AF compared to PVI alone.
- The presence of rapid PW activity may identify patients with persistent AF likely to benefit from PWI.

BACKGROUND: Advanced generation ablation technologies have been developed to achieve more effective pulmonary vein isolation (PVI) and minimize arrhythmia recurrence after atrial fibrillation (AF) ablation.

METHODS: We randomly assigned 346 patients with drug-refractory paroxysmal AF to contact force–guided radiofrequency ablation (CF-RF; n=115), 4-minute cryoballoon ablation (Cryo-4; n=115), or 2-minute cryoballoon ablation (Cryo-2; n=116). Follow-up was 12 months. The primary outcome was time to first documented recurrence of symptomatic or asymptomatic atrial tachyarrhythmia (AF, atrial flutter, or atrial tachycardia) between days 91 and 365 after ablation or a repeat ablation procedure at any time. Secondary end points included freedom from symptomatic arrhythmia and AF burden. All patients received an implantable loop recorder.

RESULTS: One-year freedom from atrial tachyarrhythmia defined by continuous rhythm monitoring was 53.9%, 52.2%, and 51.7% with CF-RF, Cryo-4, and Cryo-2, respectively (P=0.87). One-year freedom from symptomatic atrial tachyarrhythmia defined by continuous rhythm monitoring was 79.1%, 78.2%, and 73.3% with CF-RF, Cryo-4, and Cryo-2, respectively (P=0.26). Compared with the monitoring period before ablation, AF burden was reduced by a median of 99.3% (interquartile range, 67.8%–100.0%) with CF-RF, 99.9% (interquartile range, 65.3%–100.0%) with Cryo-4, and 98.4% (interquartile range, 56.2%–100.0%) with Cryo-2 (P=0.36). Serious adverse events occurred in 3 patients (2.6%) in the CF-RF group, 6 patients (5.3%) in the Cryo-4 group, and 7 patients (6.0%) in the Cryo-2 group, with no significant difference between groups (P=0.24). The CF-RF group had a significantly longer procedure duration but significantly shorter fluoroscopy exposure (P<0.001 vs cryoballoon groups).

*Additional CIRCA-DOSE Study Investigators are listed in the Appendix

- **CIRCA** - Cryoballoon vs. Contact-force Irrigated Radiofrequency Catheter Ablation for AF
- **DOSE** - DOuble Short (2-minute) vs. Standard (4-minute) cryoapplication Exposure
- **Continuous cardiac monitoring**

Atrial Fibrillation Progression After Cryoablation vs. Radiofrequency Catheter Ablation

- **346 patients with drug-refractory paroxysmal AF**
- **Randomized to:**
  - Contact-force guided RF ablation (CF-RF, 115)
  - 4-minute cryoballoon ablation (CRYO-4, 115)
  - 2-minute cryoballoon ablation (CRYO-2, 116)
- **Followed for:**
  - Median 944.0 days (interquartile range [IQR], 612.5 to 1104)
- **Endpoints:**
  - Progression to Persistent AF (AF episode lasting 7 days, as detected by ILR)
  - Recurrence of Atrial Tachyarrhythmia (AT/AF/AFL) > 30s
  - AF Burden (percent time in AF)

Atrial Fibrillation Progression After Cryoablation vs. Radiofrequency Catheter Ablation

- **Progression to Persistent Atrial Tachyarrhythmia**

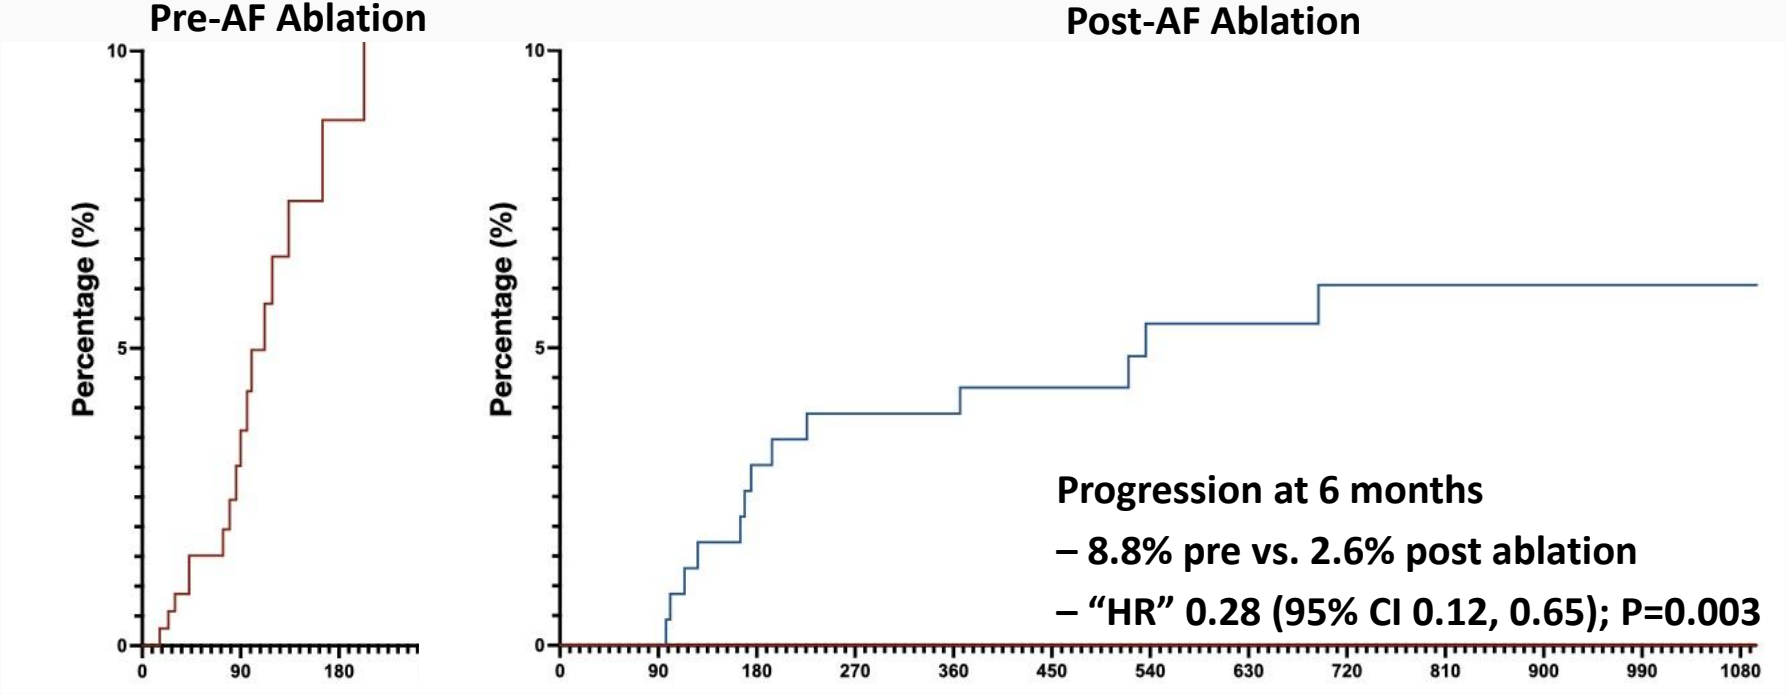
HR 4.54 (95% CI 1.44, 14.32)#

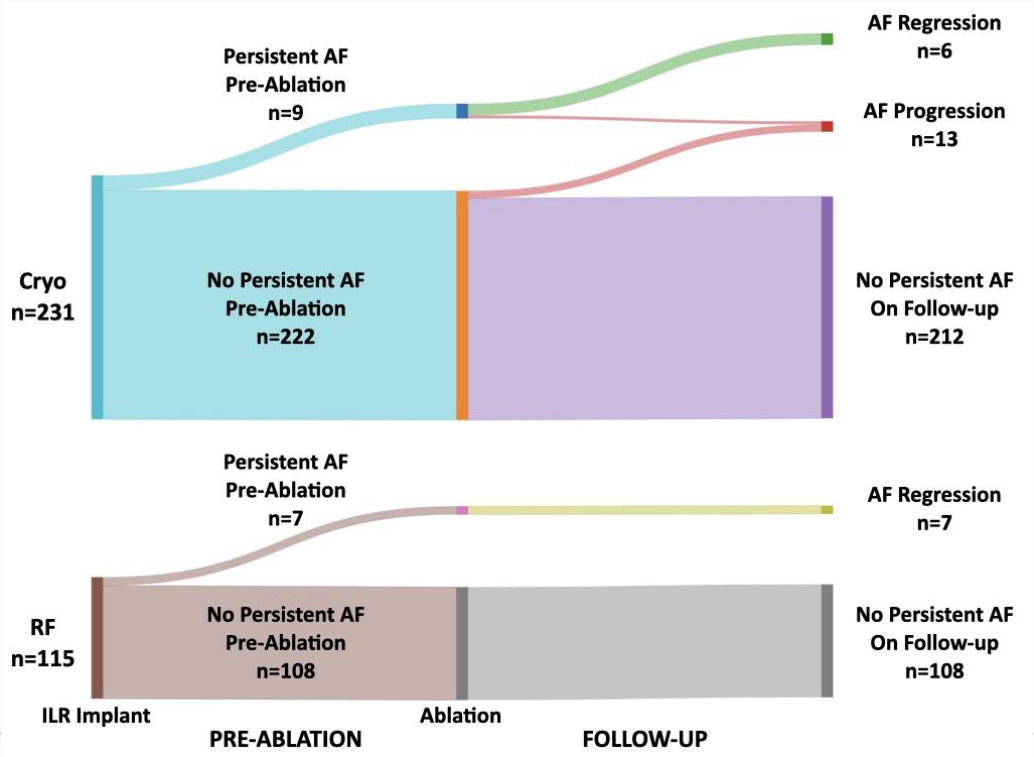
Atrial Fibrillation Progression After Cryoablation vs. Radiofrequency Catheter Ablation

- **Atrial Fibrillation Progression Pre-Post Ablation**



Atrial Fibrillation Progression After Cryoablation vs. Radiofrequency Catheter Ablation

- **Atrial Fibrillation Regression**



Atrial Fibrillation Progression After Cryoablation vs. Radiofrequency Catheter Ablation

a. Cryoballoon ablation and contact-force guided radiofrequency ablation are equally efficacious in:

a. Preventing AF recurrence on prolonged follow-up.

b. Reducing the long-term burden of AF as assessed by continuous cardiac monitoring.

b. Atrial fibrillation progression was observed less frequently after radiofrequency ablation compared to cryoballoon ablation.

c. A significant number of patients who progressed to persistent AF while awaiting ablation experienced “regression” post ablation

DANPACE II

Minimized atrial pacing and risk of atrial fibrillation in sinus node dysfunction

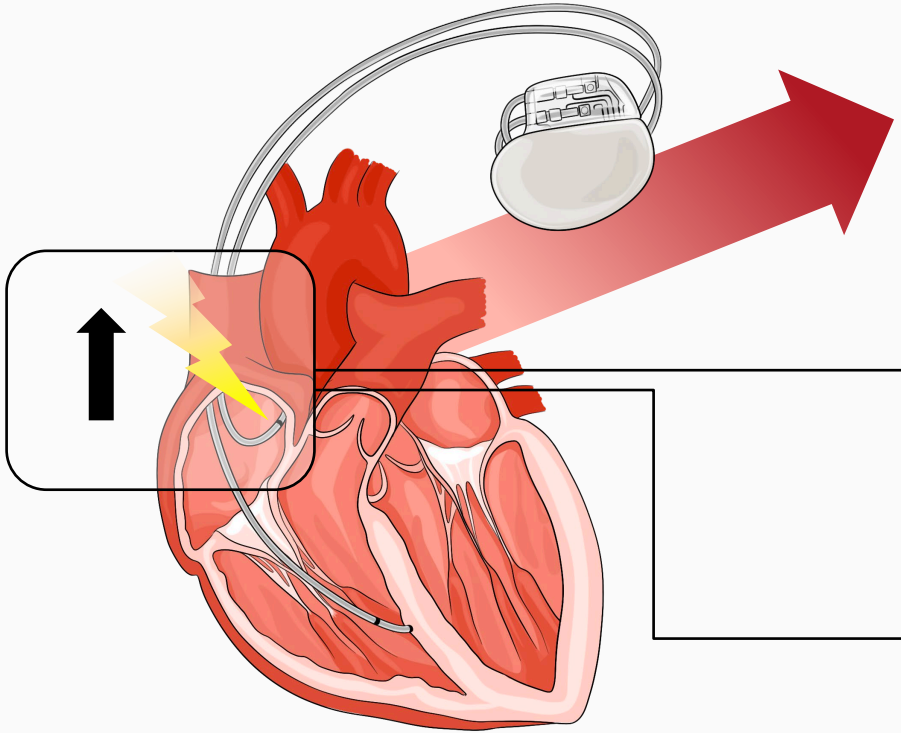
Assoc. Prof. Mads Brix Kronborg, MD PhD DMSc
On behalf of the DANPACE II investigators

08.28.2023

AARHUS UNIVERSITY HOSPITAL
AARHUS UNIVERSITY

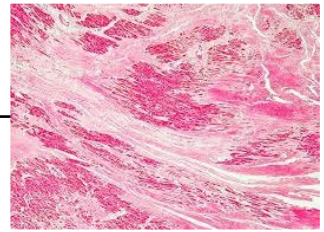
Background

Does minimized atrial pacing in patients with sinus node dysfunction reduce the risk of atrial fibrillation?



Prolongation and abnormal propagation?

OR



Progressive atrial disease?

DICTATE-AHF

Efficacy and Safety of Dapagliflozin in Acute Heart Failure

NCT04298229

Zachary Cox, PharmD

Professor, Lipscomb University College of Pharmacy, USA

Department of Pharmacy, Vanderbilt University Medical Center

On behalf of DICTATE-AHF Investigators

August 28, 2023

Background

Two Goals for Acute Heart Failure

1) Decongestion

2) GDMT Optimization

→ Improve Post-DC Outcomes

Loop + Acetazolamide	✓	⊘	No Improvement
Loop + Thiazide	✓	⊘	No Improvement
Loop + SGLT2i	?	✓	Improved Outcomes

Background

- **Concerns of early in-hospital SGLT2 inhibitor SAFETY:**
  - Hypoglycemia
  - Ketoacidosis
  - Worsening renal function
  - Genitourinary infections
  - Questionable magnitude of diuretic and natriuretic benefit

Early addition of Dapagliflozin is a potential strategy to improve achievement of both primary AHF therapeutic goals, but **efficacy and safety** are unknown

DICTATE-AHF Design

- Investigator-initiated, multicenter, prospective, randomized, open-label study funded by AstraZeneca

  Objective efficacy outcomes and blinded assessment of safety outcomes

- 240 Patients hospitalized with hypervolemic AHF randomized within 24 hours of presentation
  - Regardless of LVEF
  - Beginning April 2020, only patients with Type 2 diabetes mellitus were included
    - September 2021 - protocol amended to include:
      - With or without type 2 diabetes mellitus
      - eGFR $\geq$ 25 mL/min/1.73m^2

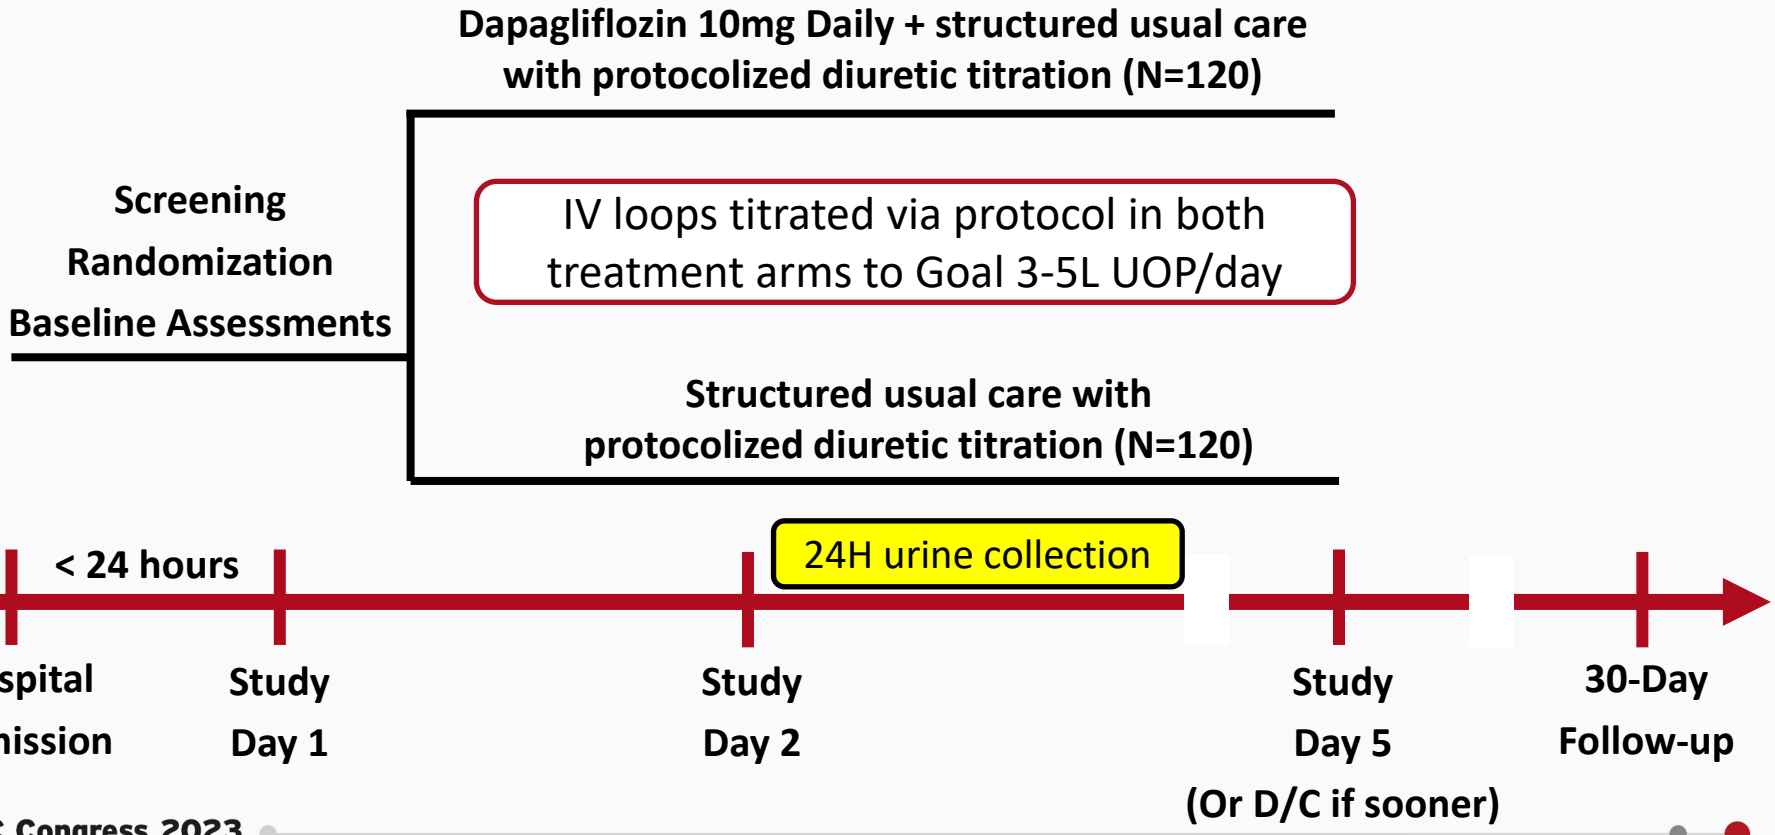
Key Inclusion Criteria

- Age of 18 years or older
- Randomized within 24 hours of presentation hypervolemic AHF:
  - ≥2 objective measures of hypervolemia
- Planned or current use of IV loop diuretic therapy
- eGFR ≥ 25 mL/min/1.73m^2

Key Exclusion Criteria

- Type 1 diabetes
- Serum glucose < 80mg/dL
- Systolic blood pressure < 90mmHg
- IV inotropic therapy
- History of diabetic ketoacidosis
- Inability to perform standing weights or measure urine output accurately

DICTATE-AHF



Dapagliflozin 10mg Daily + structured usual care with protocolized diuretic titration (N=120)
Screening
Randomization
Baseline Assessments
IV loops titrated via protocol in both treatment arms to Goal 3-5L UOP/day
Structured usual care with protocolized diuretic titration (N=120)
< 24 hours
24H urine collection
Hospital Admission
Study Day 1
Study Day 2
Study Day 5 (Or D/C if sooner)
30-Day Follow-up

Study Outcomes

Primary Outcome

$$\text{Diuretic Efficiency} = \frac{\text{Cumulative weight change (kg)}}{\text{Cumulative loop diuretic dose (mg)}}$$

- Calculated until Day-5 or hospital discharge if sooner
- Expressed as *kg/40mg IV Furosemide equivalents*
- Compared across treatment assignment using a proportional odds regression model adjusting for baseline weight

Study Outcomes

Secondary Outcomes adjudicated by blinded committee

- Incidence of worsening HF during hospital stay
- HF-related or diabetes-related 30-day readmissions

Safety Outcomes adjudicated by blinded committee

- Incidence of diabetic ketoacidosis
- Prolonged hospitalization for hypotension
- Prolonged hospitalization for hypoglycemia
- Change in eGFR from baseline to end-of-study

Select Exploratory Outcomes

- Measures of natriuresis and diuresis
- Hospital length of stay

Baseline Characteristics

Characteristic	Total Population (N=238)	Usual Care (N=119)	Dapagliflozin (N=119)
Age (yrs)	65 (56 – 73)	64 (55 – 74)	65 (56 – 73)
Male Sex	61%	56%	66%
White Race	68%	71%	66%
T2DM	71%	71%	71%

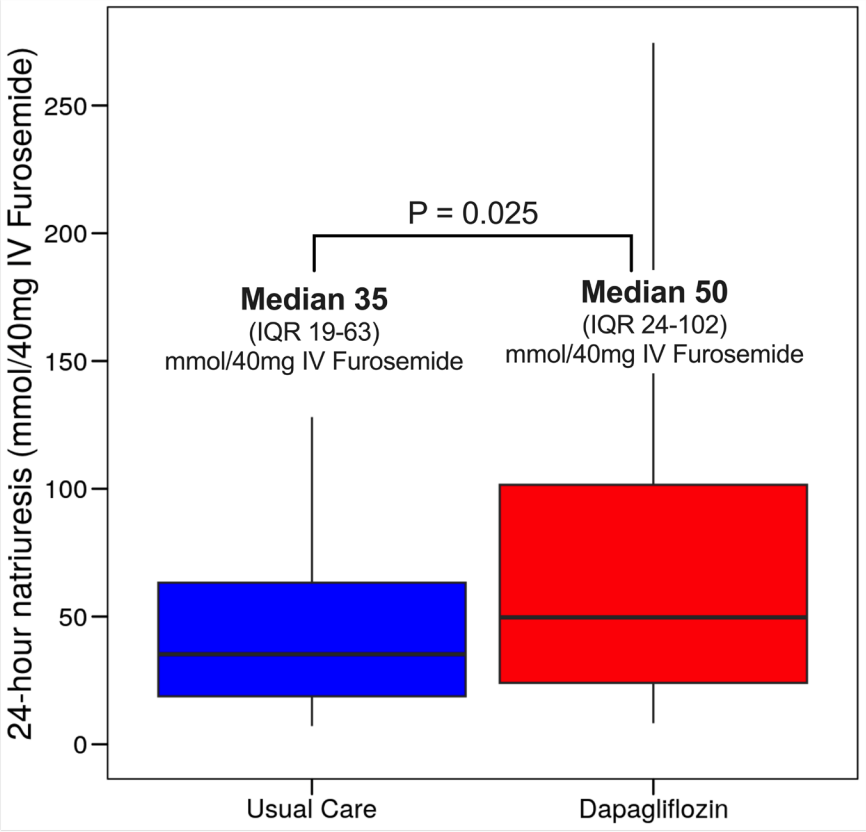
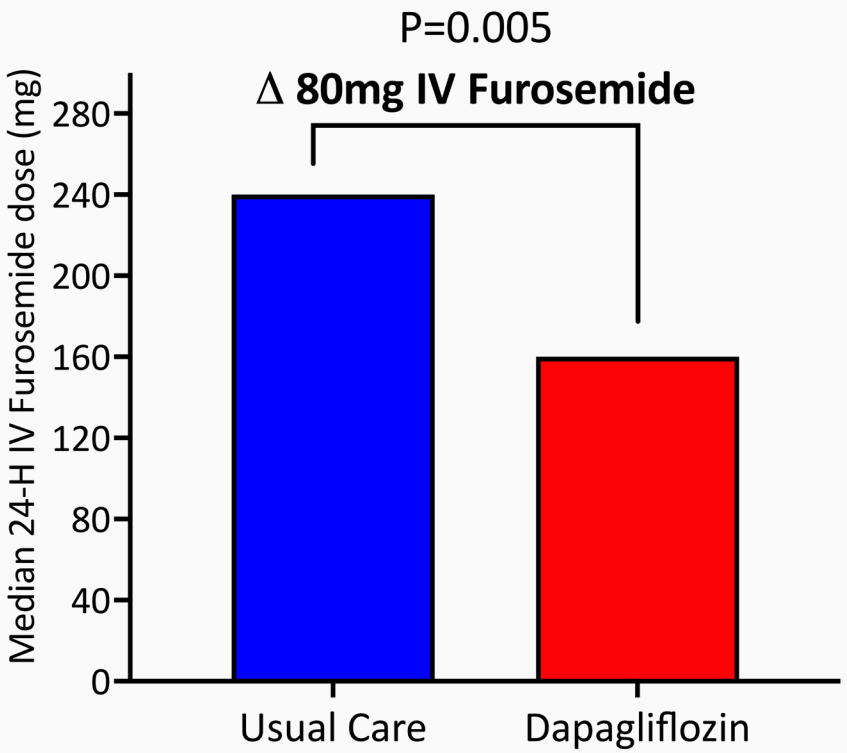
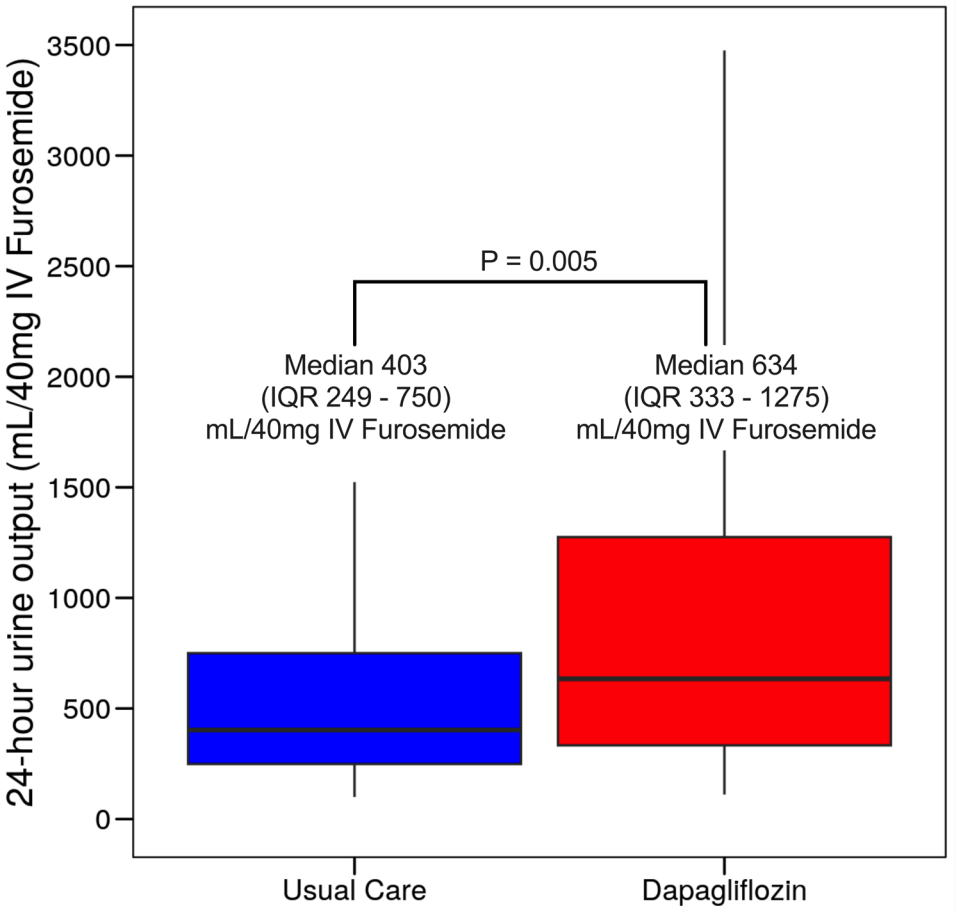
Improved 24-Hour Natriuresis with Dapagliflozin

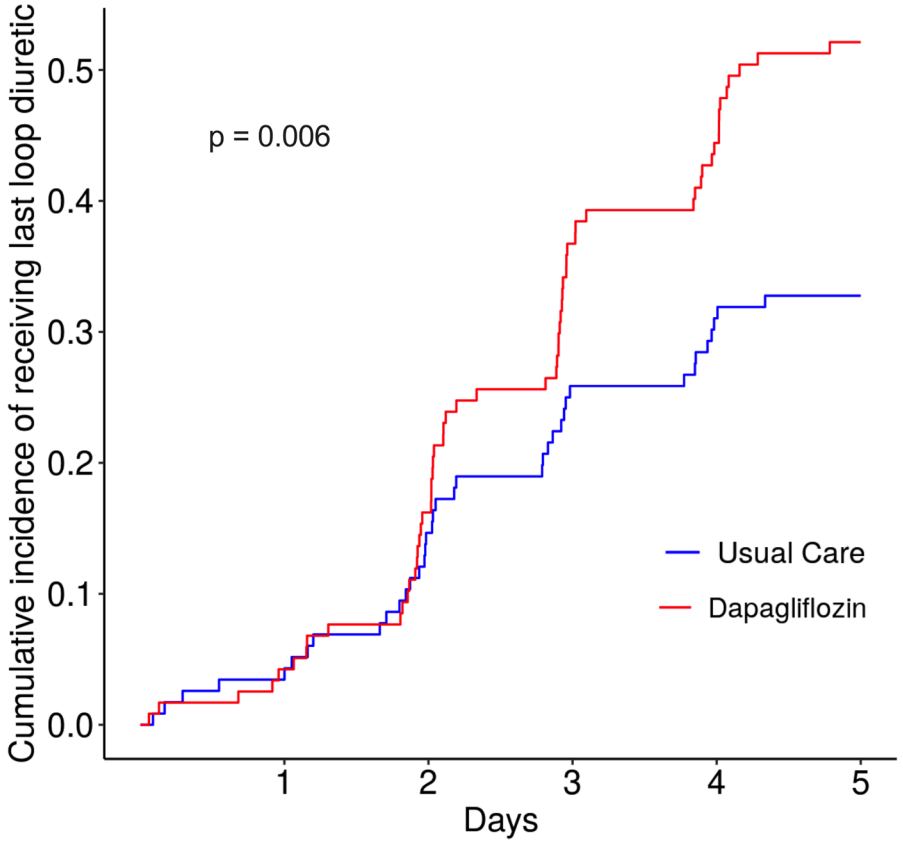


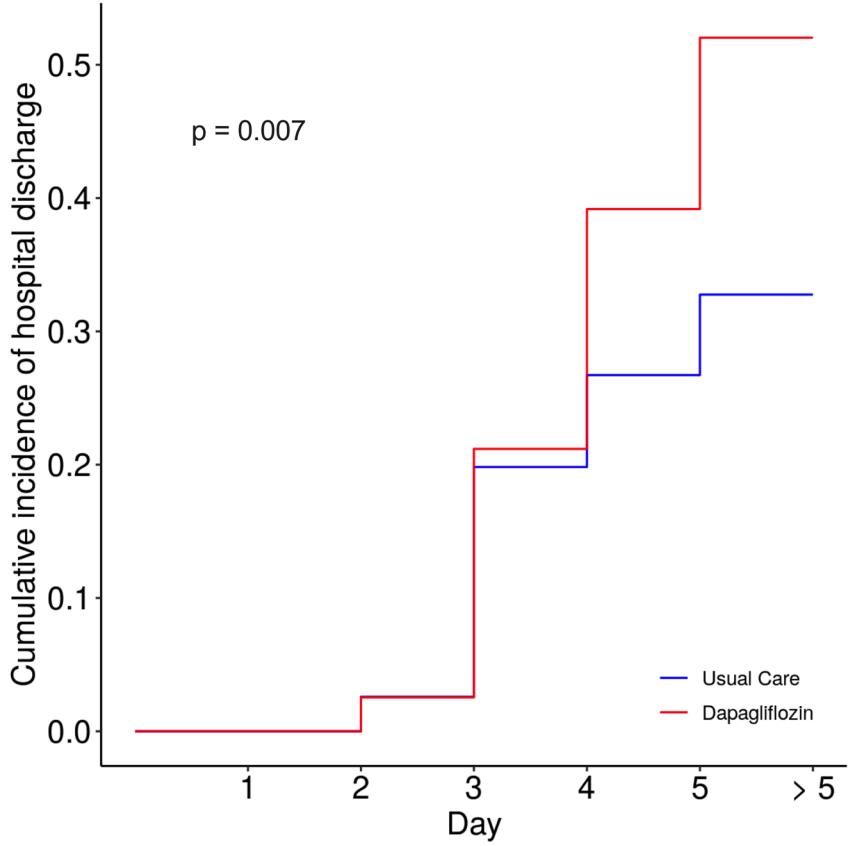


Improved 24-Hour Diuresis with Dapagliflozin



Faster Time to Oral Diuretic Transition and Discharge





Secondary Outcomes

Secondary Outcomes, N	Usual Care	Dapagliflozin
Worsening heart failure	3	4
30-day hospital readmission for ADHF or diabetes-related reasons	8	7
ADHF-related readmission	8	6
Diabetes-related readmission	0	1

Safety Outcomes and Adverse Events

Safety Outcomes	Usual Care	Dapagliflozin
Ketoacidosis	0	0
Symptomatic hypotension	4	2
Prolonged hospitalization for hypotension	1	1
Hypoglycemia	9	7
Prolonged hospitalization for hypoglycemia	0	0
Genitourinary tract infections	1	0
Change in eGFR (mL/min/1.73m^2)	-3.0 (-9 to 2)	-2.0 (-10 to 4)

Conclusions

1. Dapagliflozin had a strong signal to improve diuretic efficiency supported by:
   - Increased natriuresis and diuresis per 40mg of IV furosemide
   - Decreased total dose and duration of loop diuretics required
   - Decreased time to hospital discharge
2. Early dapagliflozin initiation was safe across all diabetic and cardiorenal outcomes

Totality of DICTATE-AHF data supports the early initiation of dapagliflozin in AHF to safely facilitate decongestion and GDMT optimization

Background

Acetazolamide + loop diuretics vs. loop diuretics alone associated with more successfull decongestion after 3 days

Mullens W, Dauw J et al. N Engl J Med. 2022;387:1185-1195

Aims

1. To evaluate the treatment effect of acetazolamide according to baseline renal function

2. To evaluate the effect of acetazolamide on renal function and its relation with outcomes

Methods

ADVOR
A multicenter, randomized, double-blind, placebo-controlled, trial

519 acute decompensated heart failure patients

500 mg acetazolamide IV + loop diuretics IV (*oral home dose bid*)
vs.
placebo + loop diuretics IV (*oral home dose bid*)

Primary endpoint: successful decongestion after 3 days without need for diuretic therapy escalation

Mullens W, Dauw J et al. N Engl J Med. 2022;387:1185-1195

Methods: patient selection

Main inclusion criteria

- Admitted with ADHF
- At least 1 sign of volume overload (edema, pleural effusion*, ascites°)

  To be confirmed with radiography or ultrasonography of the chest or ultrasonography of the abdomen°*
- At least 1 month maintenance dose of oral loop diuretics (≥ 40 mg furosemide)
- NT-proBNP > 1000 pg/ml or BNP > 250 pg/ml

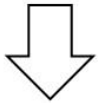
Main exclusion criteria

- Acetazolamide maintenance therapy
- Treatment with SGLT2i
- Systolic blood pressure < 90 mmHg
- eGFR < 20 ml/min

Mullens W, Dauw J et al. N Engl J Med. 2022;387:1185-1195

Methods: congestion score

EDEMA	No edema (score 0)	Trace edema (pitting disappear immediately) (score 1)	Clear pitting edema (score 2)	Visual deformation above ankle (score 3)	Visual deformation above knee (score 4)
PLEURAL EFFUSION (to be confirmed by chest X-ray or ultrasound on admission if suspected)	No pleural effusion (score 0)	Minor (non-amenable for punction) pleural effusion (score 2)		Major (amenable for punction) pleural effusion (score 3)	
ASCITES (to be confirmed by ultrasound on admission if suspected)	No ascites (score 0)	Minor ascites, only detected by echography (score 2)		Significant ascites (score 3)	



Successful decongestion

Continue IV diuretic therapy

Mullens W, Dauw J et al. N Engl J Med. 2022;387:1185-1195

Results: eGFR distribution

p=0.032

WRF -

HR 0.51

95% CI [0.27-0.94]

p=0.032

P for interaction 0.805

Conclusion

- The addition of acetazolamide to standardized loop diuretics in patients with acute decompensated heart failure is associated with a higher incidence of successful decongestion **across the full (≥20) eGFR range**
- All acetazolamide treated patients had higher natriuresis and diuresis, but the effect was even higher in patients with lower eGFR
- Acetazolamide was associated with more worsening renal function, but no difference in serum creatinine after 3 months
- No benefit on combined endpoint heart failure hospitalization or mortality
- Worsening renal function was only associated with worse outcomes in patients with persistent congestion

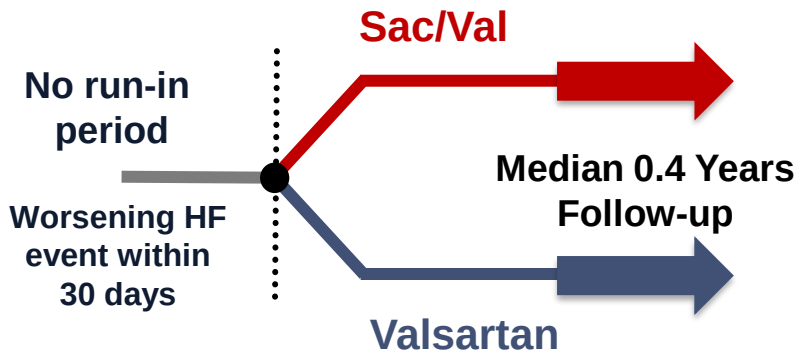
Entry criteria	Study design

PARAGLIDE-HF (n=466)

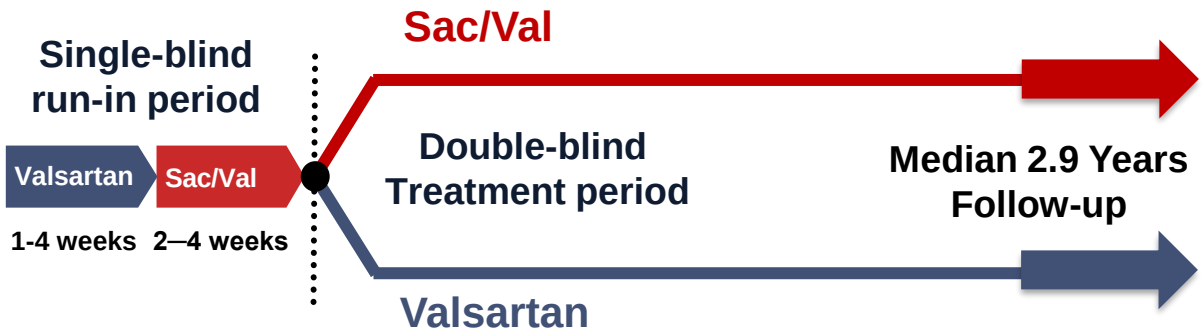
- Age ≥18 years
- HF with LVEF >40%
- Current or recent worsening HF event
- Elevated natriuretic peptides
- **eGFR ≥20mL/min/1.73 m²**



Mentz RJ, *et al. J Card Fail* 2023

PARAGON-HF (n=4,796)

- Age ≥50 years
- HF with LVEF ≥45%
- NYHA class II-IV
- Elevated natriuretic peptides
- Structural heart disease
- **eGFR ≥25mL/min/1.73 m²***



Solomon SD, *et al. JACC HF* 2017

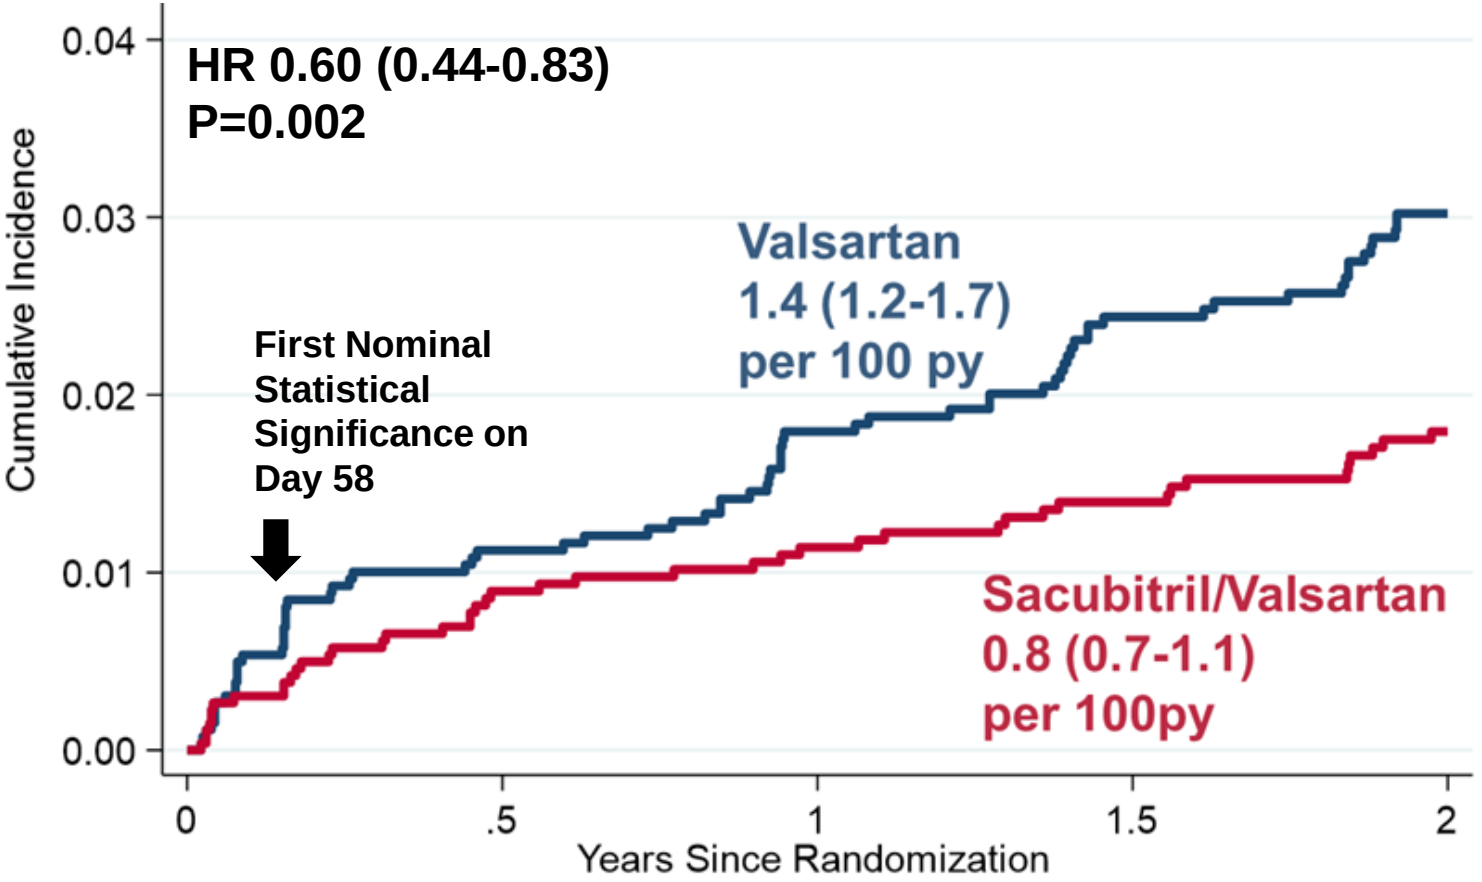
* ≥30 mL/min/1.73 m² at screening and ≥25 mL/min/1.73 m² at randomization and without greater than a 35% reduction in eGFR during either run-in period

Baseline Characteristics

	Sac/Val (n=2,640)	Val (n=2,622)
Age (years)	72 ± 9	73 ± 9
Men	48%	48%
Black race	4%	4%
LVEF (%)	57 ± 8	57 ± 8
Hypertension	96%	95%
Atrial fibrillation or flutter	53%	54%
Systolic blood pressure (mmHg)	131 ± 16	131 ± 16
Body mass index (kg/m^2)	31 ± 6	31 ± 6
eGFR (mL/min/1.73m^2)	62 ± 19	62 ± 19
Serum potassium (mmol/L)	4.5 ± 0.5	4.5 ± 0.5
NT-proBNP (pg/mL)	945 [490, 1700]	947 [461, 1714]
ACEi or ARB	85%	86%
MRA	25%	27%
β-blocker	80%	79%
SGLT2i	2%	2%

Renal Composite: Nominal Significance within 2 months

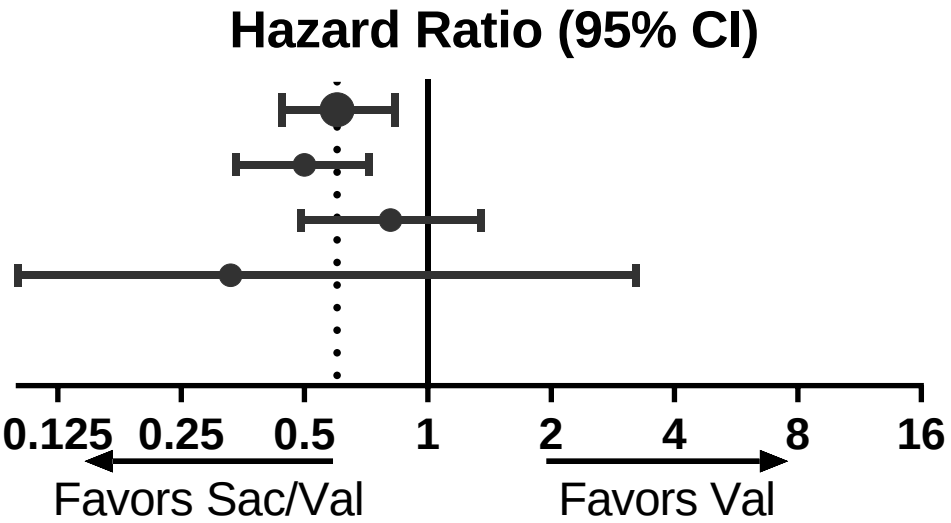
Time to first ≥50% decline in eGFR from baseline, ESRD, or renal death



Renal Composite: Contribution of Each Component to Benefit

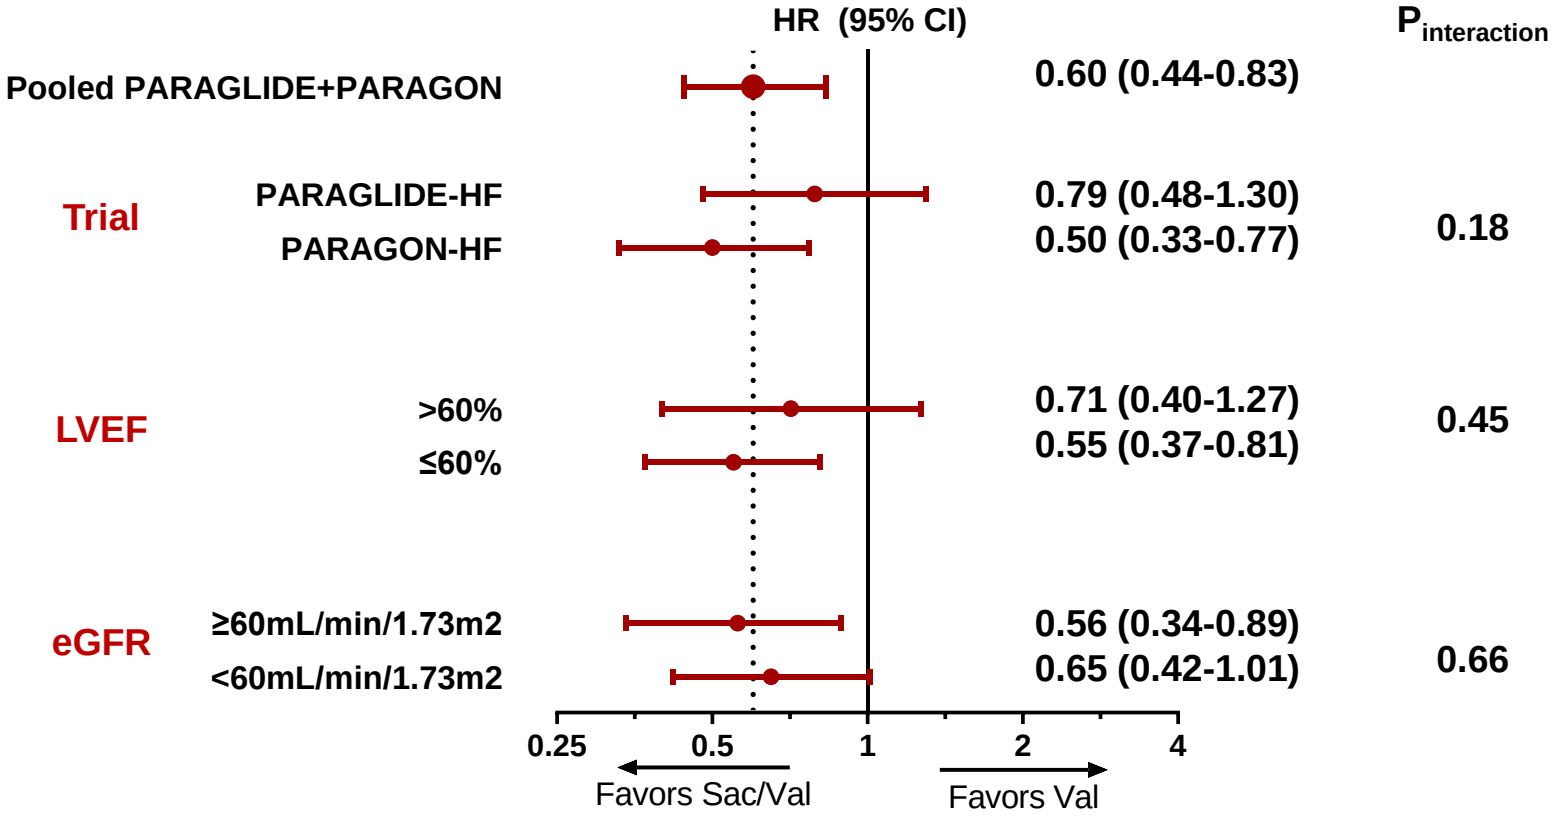
Time to first ≥50% decline in eGFR from baseline, ESRD, or renal death

	# of Events Sac/Val	# of Events Val
Renal Composite Endpoint	60	99
≥50% decline in eGFR	41	82
ESRD	27	34
Renal Death	1	3



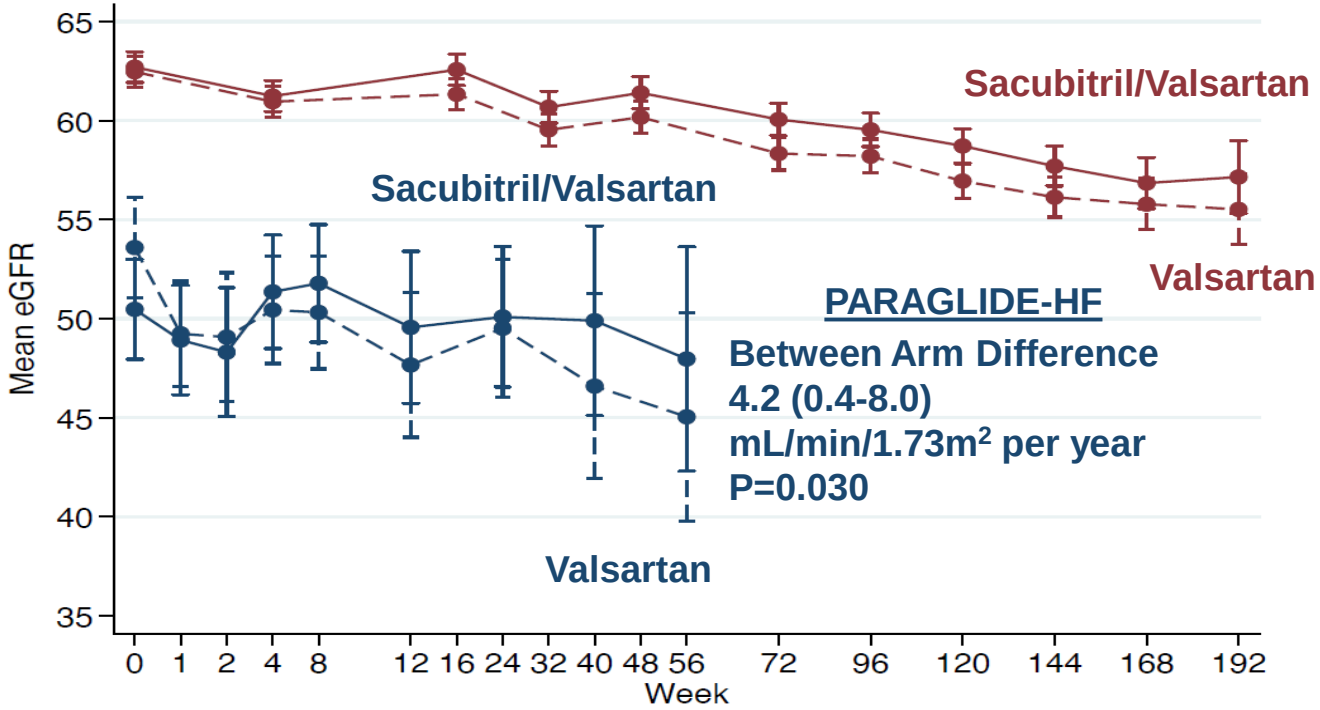
The sum of the individual component events exceed the number of events of the renal composite endpoint as more than one component may meet the endpoint definition at the same timepoint

Renal Composite: Consistent Across Key Subgroups



Treatment effects on the renal composite endpoint were consistent across key demographics, clinical characteristics, and background medications

Sacubitril/Valsartan Slows Decline in eGFR over Time Compared with Valsartan



PARAGON-HF

Between Arm Difference
0.6 (0.3-0.8)
mL/min/1.73m^2 per year
P<0.001

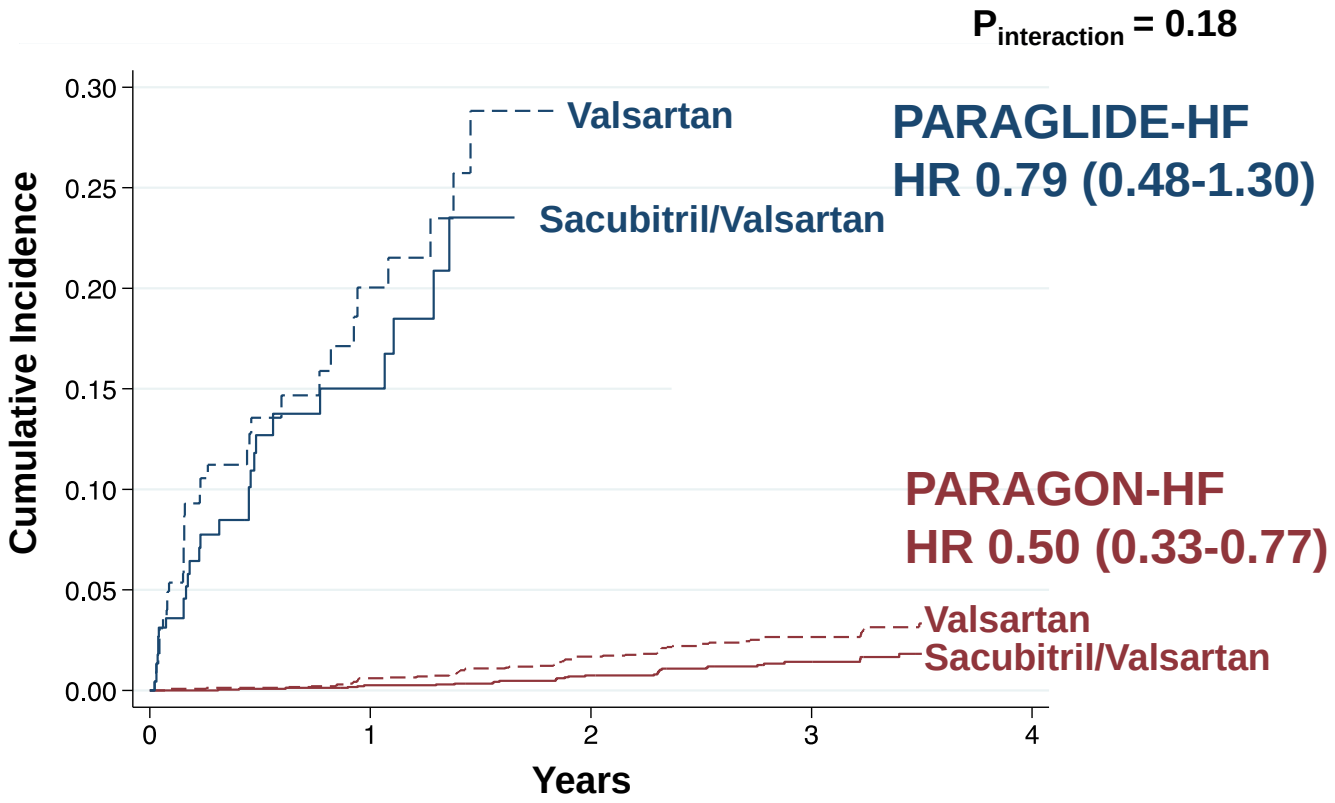
Summary: Pooled Analyses of PARAGLIDE-HF & PARAGON-HF

- Sacubitril/valsartan reduced clinically relevant renal events in both high-risk patients hospitalized for acute HF and those in ambulatory care
- These renal benefits were observed rapidly with statistically significant reductions in renal events first observed within months of treatment initiation and extended across all key subgroups
- Sacubitril/valsartan slowed decline in eGFR over time compared with valsartan

Among both hospitalized and ambulatory patients with HF with mildly reduced or preserved ejection fraction, sacubitril/valsartan reduced risks of renal events and slowed decline in eGFR over time compared with valsartan.

Renal Composite: Consistent Between Trials

Time to first ≥50% decline in eGFR from baseline, ESRD, or renal death



PUSH-AHF trial

#ESCCongress

Natriuresis guided therapy in acute heart failure

Conclusion

A pragmatic natriuresis guided diuretic approach in patients with acute heart failure (AHF) significantly increases 24-hour natriuresis without impacting all-cause mortality or HF rehospitalisation.

Impact on clinical practice

Clinicians should consider natriuresis guided diuretic therapy as a first step to a personalised treatment approach in patients with AHF to improve decongestion.

Study objectives

The PUSH-AHF trial investigated the effectiveness of natriuresis guided diuretic therapy on natriuresis and clinical outcomes in patients with AHF.

Study population

Patients

- AHF requiring treatment with intravenous (IV) loop diuretics

The inclusion and exclusion criteria were intentionally broad to enrol a contemporary, representative, all-comer AHF population.

Where?

University Medical Centre Groningen, the Netherlands

Primary endpoints: p<0.025 for each was considered statistically significant

24-hour natriuresis

409 ± 178 mmol

345 ± 202 mmol

p=0.0061

Combined endpoint of time to all-cause mortality or HF rehospitalisation at 180 days

46 patients (31%)

50 patients (31%)

Hazard ratio 0.92; 95% CI 0.62 to 1.38; p=0.6980

Who and what?

310 patients

randomised 1:1

Natriuresis guided diuretic therapy

Twice daily IV diuretic therapy

Spot urinary sodium determined at 2, 6, 12, 18, 24 and 36 hours after starting IV loop diuretics

Therapy intensified using a prespecified stepwise approach if response insufficient:

- spot urinary sodium <70 mmol
- and/or diuresis <150 ml/hour

Standard of care

Twice daily IV diuretic therapy

Physicians blinded to urinary sodium levels

STEP-HFpEF trial

#ESCCongress

Once-weekly semaglutide in people with HFpEF and obesity

Conclusion

Semaglutide improves heart failure-related symptoms and physical function and results in greater weight loss compared with placebo in patients with heart failure with preserved ejection fraction (HFpEF) and obesity.

Impact on clinical practice

The results indicate that obesity is not simply a comorbidity in patients with HFpEF but a root cause and a target for therapeutic intervention.

Study objectives

The STEP-HFpEF trial tested the hypothesis that treatment with semaglutide can significantly improve symptoms, physical limitations and exercise function, in addition to weight loss, in patients with HFpEF and obesity.

Study population

HFpEF patients

- left ventricular ejection fraction ≥45%
- body mass index ≥30 kg/m2
- HF symptoms
- functional limitations (New York Heart Association functional class II–IV and Kansas City Cardiomyopathy Questionnaire Clinical Summary Score [KCCQ-CSS] <90 points)

Where?

13 countries in Asia, Europe, North America and South America

96 sites

Who and what?

529 patients

randomised 1:1

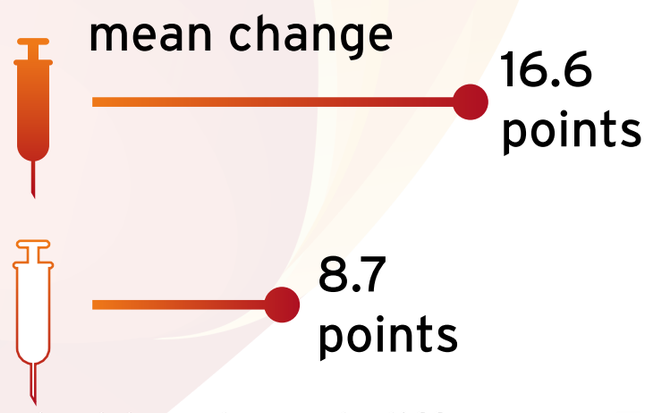
once-weekly for 52 weeks

semaglutide 2.4 mg

placebo

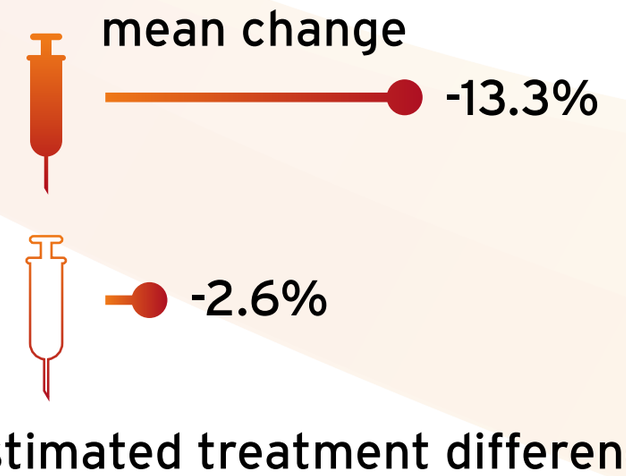
Primary endpoints

change from baseline to week 52 in KCCQ-CSS



estimated treatment difference 7.8 points
95% CI 4.8 to 10.9
p<0.001

change from baseline to week 52 in body weight



estimated treatment difference -10.7%
95% CI -11.9% to -9.4%

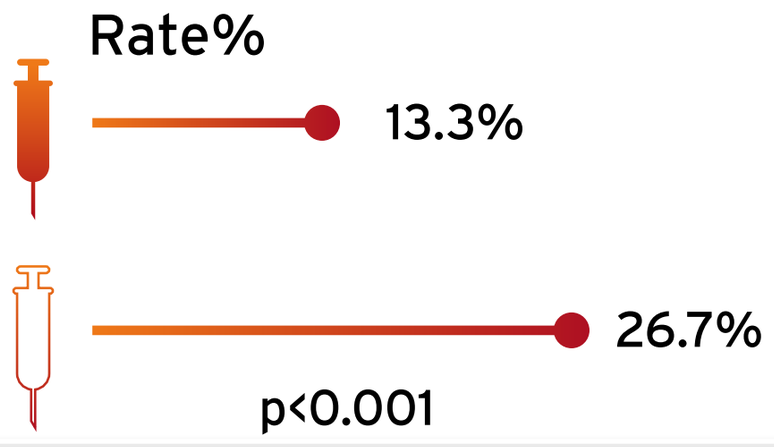
Serious adverse events



p<0.001

ESC

CASTLE-HTx trial

#ESCCongress

Catheter ablation versus medical therapy to treat atrial fibrillation in end-stage heart failure

Conclusion

Atrial fibrillation (AF) ablation is associated with lower rates of death, urgent heart transplantation or left ventricular assist device (LVAD) implantation compared with medical therapy in patients with end-stage heart failure (HF).

Impact on clinical practice

Patients with end-stage HF eligible for heart transplantation have been excluded from major trials, leaving them with no recommendations or evidence for the optimal treatment of AF and advanced HF. The trial showed that AF ablation improves outcomes in this group.

Study objectives

The CASTLE-HTx trial tested whether AF ablation is superior to medical therapy concerning mortality and need for urgent transplantation or LVAD implantation.

Study population

Patients

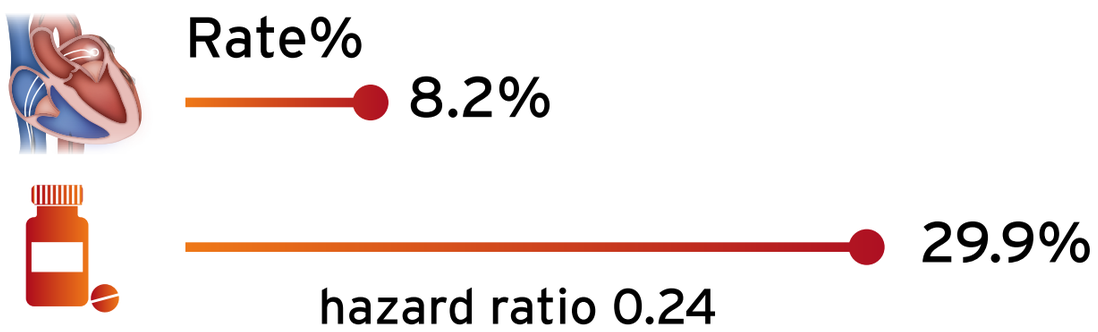
- with symptomatic AF
- with end-stage HF eligible for heart transplantation
- in New York Heart Association functional class II, III, or IV
- had left ventricular ejection fraction (LVEF) ≤35%
- were fitted with a cardiac device for continuous monitoring

Where?

Heart and Diabetes Center North Rhine-Westphalia, Bad Oeynhausen, Germany

Primary endpoint

Composite of all-cause mortality, worsening HF requiring urgent heart transplantation, or implantation of LVAD.



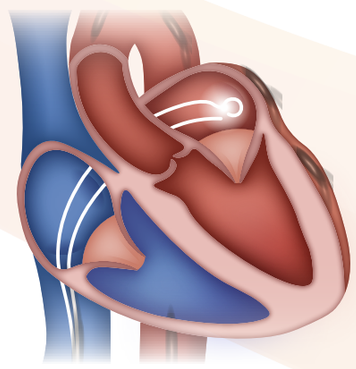
Who and what?

194 patients

randomised 1:1

First-time catheter ablation of AF

Medical therapy for AF



Both groups received guideline-directed HF therapy.

The study was stopped for efficacy by the Data Safety Monitoring Board 1 year after randomisation was completed.

HEART-FID

Efficacy and Safety of Ferric Carboxymaltose as Treatment For HF With Iron Deficiency

Double-Blind, Multicenter, Placebo-Controlled, Industry Sponsored, Randomized Trial

OBJECTIVE: To assess the effect of Ferric Carboxymaltose (FCM) administration on safety and outcomes in patients with heart failure (HF).

3,065 PATIENTS

INCLUSION CRITERIA:

- Patients Iron Deficiency (Ferritin <100 ng/ml or 100-300 ng/ml with TSAT <20%)
- HFrEF (<40%) on maximally tolerated GDMT
- HF hospitalization within the last 12 months or Nt-proBNP > 600pg/mL (>1000 pg/mL if in atrial fibrillation)

1,532 PATIENTS GIVEN WEIGHT-BASED INFUSIONS OF FCM

VS.

1,533 PATIENTS GIVEN INFUSIONS OF SALINE

PRIMARY ENDPOINT

THE HIERARCHICAL COMPOSITE OF MORTALITY, HF HOSPITALIZATION AND CHANGE IN 6-MINUTE WALK DISTANCE FAVORED THE TREATMENT ARM (P=0.019).

SECONDARY ENDPOINTS

ALL-CAUSE MORTALITY WAS REDUCED (8.6% VS. 10.3%)

HYPERSENSITIVITY/ANAPHYLACTOID REACTIONS WERE INCREASED WITH FCM (7 VS. 1)

CONCLUSION

In patients with iron deficiency and HFrEF, treatment with FCM was safe and resulted in improvement in the hierarchical endpoint of mortality, HF hospitalization and 6-minute walk.

Mentz, R. Ferric Carboxymaltose in Heart Failure with Iron Deficiency. *New England Journal of Medicine* 2023;Aug 26:[Epublished]

ILUMIEN IV trial

#ESCCongress

OCT versus angiography

Conclusion

Optical coherence tomography (OCT)-guided percutaneous coronary intervention (PCI) leads to a larger minimum stent area but does not reduce the 2-year rate of target vessel failure compared with angiography-guided PCI.

Impact on clinical practice

OCT-guided PCI led to a larger minimum stent area, enhanced the safety of the PCI procedure and resulted in nearly a two-thirds reduction in stent thrombosis during 2-year follow-up. However, OCT guidance did not reduce the 2-year rate of target vessel failure compared with angiography-guided PCI.

Study objectives

The ILUMIEN IV trial investigated whether OCT-guided PCI is superior to angiography-guided PCI for minimum stent area and target vessel failure in complex patients and lesions.

Study population

Patients with medication-treated diabetes and/or complex lesions.

Where?

18 countries

80 sites

Who and what?

2,487 patients randomised 1:1

- OCT-guided PCI
- Angiography-guided PCI

Co-primary endpoints

post-PCI minimum stent area assessed by OCT

OCT-guided PCI	5.72 mm²	difference 0.36 mm² 95% CI 0.21 to 0.51 p<0.001
Angiography-guided PCI	5.36 mm²	

2-year rate of target vessel failure (composite of cardiac death, target vessel myocardial infarction, or ischaemia-driven target vessel revascularisation)

OCT-guided PCI	Kaplan-Meier estimated rate 7.4%	hazard ratio 0.90 95% CI 0.67 to 1.19 p=0.45
Angiography-guided PCI	8.2%	

Secondary endpoint

Stent thrombosis within 2 years

OCT-guided PCI	Rate 0.5%	hazard ratio 0.36 95% CI 0.14 to 0.91
Angiography-guided PCI	1.4%

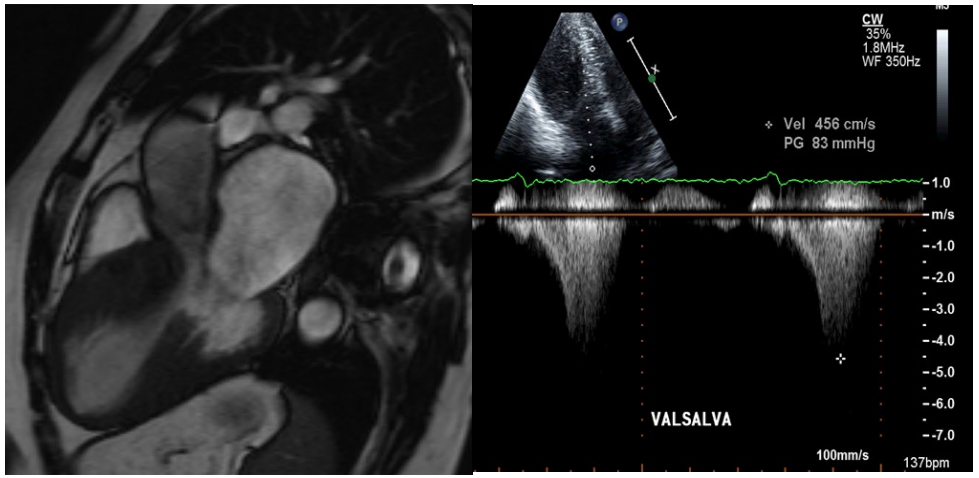
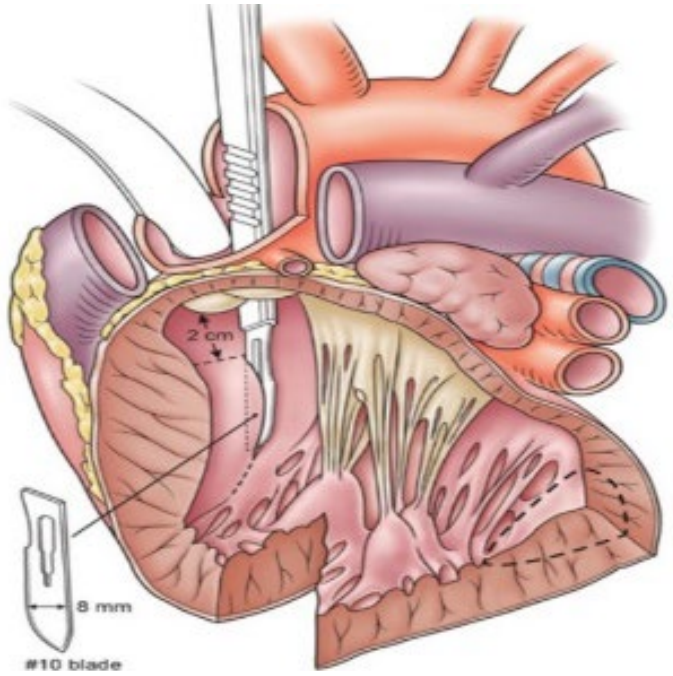
ESC Congress 2023 Amsterdam

Disclosures: Dr. Desai is a consultant for Bristol Myers Squibb, Cytokinetics, Tenaya and Medtronic
The VALOR-HCM study was funded by Bristol Myers Squibb, Princeton, NJ

Obstructive Hypertrophic Cardiomyopathy

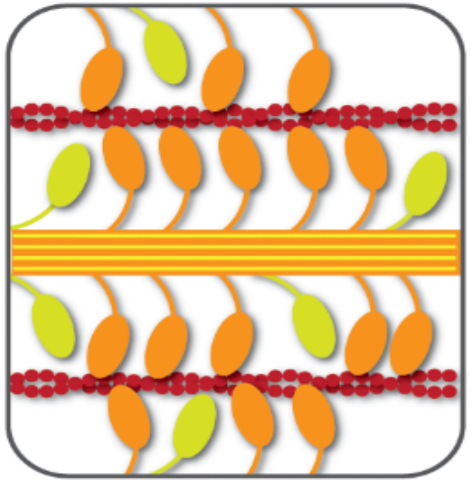
- Hypertrophic cardiomyopathy (HCM) is a myocardial disorder characterized by primary left ventricular (LV) hypertrophy
  - Two-thirds of patients have obstructive HCM
  - Current guideline-recommended medical therapies not developed specifically for HCM
- Septal reduction therapies (SRT), either surgical septal myectomy or alcohol ablation, recommended for intractable symptoms despite maximal medical therapy
  - Although SRT improves long-term survival, symptoms and quality of life, optimal results require specialized care not widely available
  - Unmet need for medical alternatives to SRT





Ommen S, Mital S et al. J Am Coll Cardiol. 2020 Dec 22;76(25):e159-e240, Maron B, Desai M et al. J Am Coll Cardiol. 2022 Feb 1;79(4):390-414, Desai M Smedira N et al. Circulation. 2013 Jul 16;128(3):209, Desai M, Smedira N et al. JAMA Network Open 2022, Olivotto et al. Lancet. 2020 Sep 12;396(10253):759-769 Desai MY et al. J Am Coll Cardiol. 2022 Jul 12;80(2):95-108

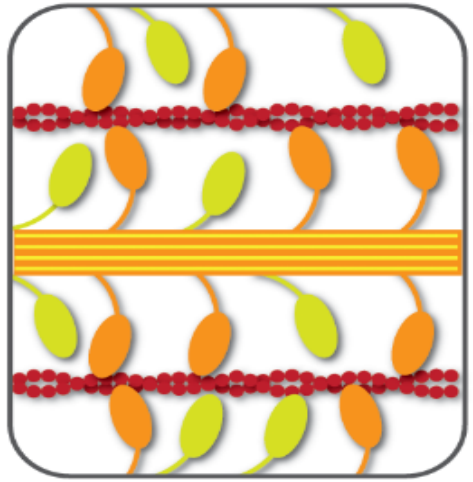
Mavacamten: First in Class Cardiac Myosin Inhibitor



HCM Sarcomere

- Hyper contractility
- Impaired relaxation
- Altered myocardial energetics

Mavacamten



HCM Sarcomere with Mavacamten

- Reduces myosin-actin cross bridges
- Attenuates hypercontractility and improve compliance and energetics

In Phase III RCTs of symptomatic obstructive HCM patients (EXPLORER-HCM and VALOR-HCM), mavacamten reduces need for SRT, improves LVOT gradient, QOL and physical functioning

Currently, clinically approved in 5 continents for use in adult symptomatic obstructive HCM patients

EXPLORER-HCM (Clinicaltrials.gov NCT03470545) and VALOR-HCM (Clinicaltrials.gov NCT04349072)

Desai MY et al. J Am Coll Cardiol. 2022 Jul 12;80(2):95-108, Desai MY et al. Circulation 2023 Mar 14;147(11):850-863, Olivotto et al. Lancet. 2020 Sep 12;396(10253):759-769, Spertus J et al. Lancet. 2021 Jun 26;397(10293):2467-2475

VALOR-HCM

Phase III placebo-controlled RCT (for 16 weeks) with placebo to mavacamten cross over starting Week 16

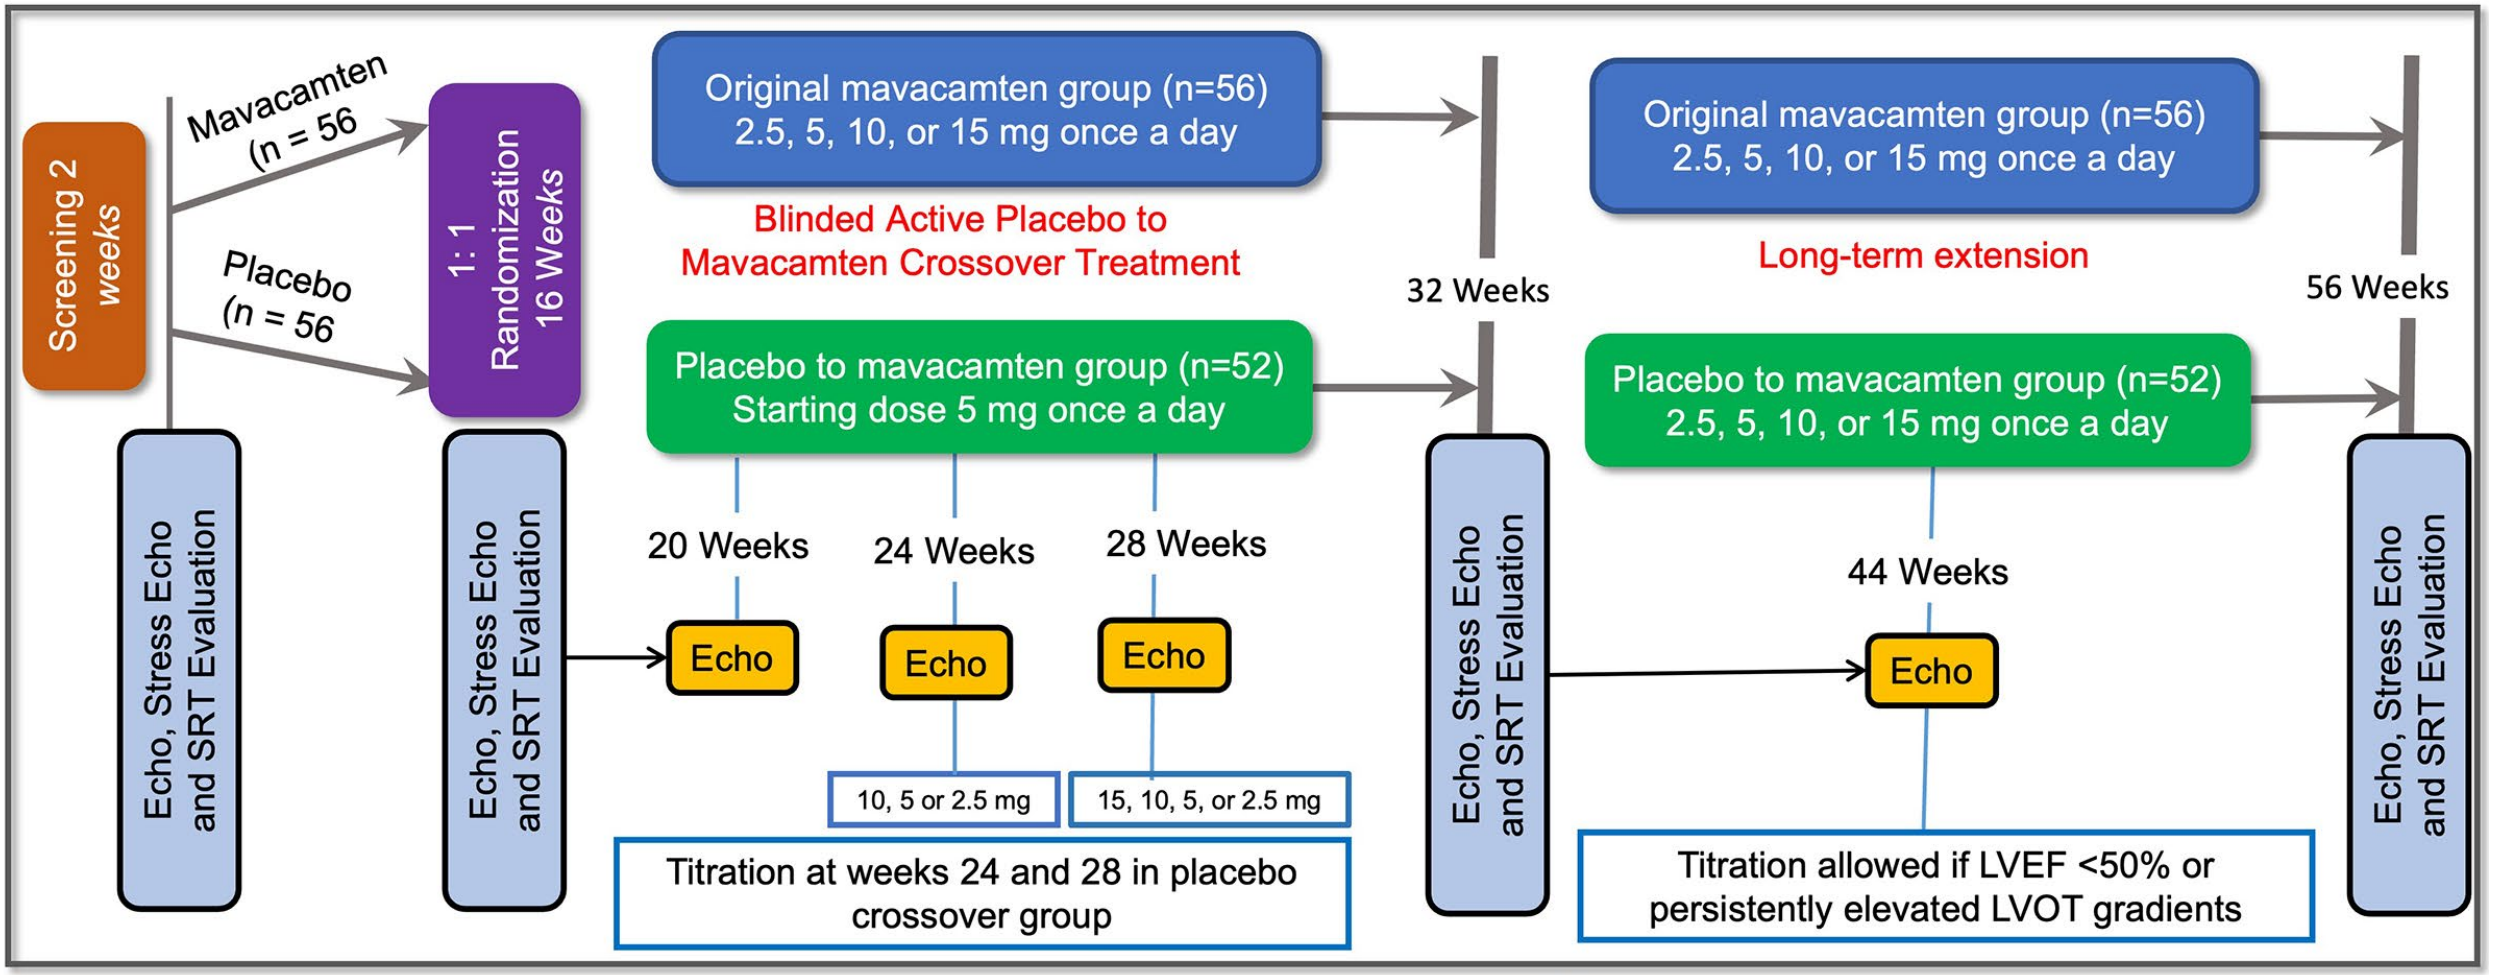
Sought to determine if addition of mavacamten to maximally-tolerated medical therapy would allow severely symptomatic oHCM patients to improve sufficiently that they no longer met guideline criteria for SRT or chose not to undergo SRT

Principal Objective of Week 56 VALOR-HCM

Report the safety and efficacy results through 56 weeks of dose-blinded treatment in patients initially randomized to mavacamten (Day 1 to Week 56) and patients initially randomized to placebo who crossed over to mavacamten for 40 weeks exposure (Week 16 to Week 56)

Desai MY et al. J Am Coll Cardiol. 2022 Jul 12;80(2):95-108
Desai MY et al. Circulation 2023 Mar 14;147(11):850-863

Study Design



Mavacamten titrated using core-lab measured ECHO LVEF and LVOT gradient at rest and Valsalva provocation

Mavacamten titrated using site measured ECHO LVEF and LVOT gradient at rest and Valsalva provocation

Key inclusion criteria

- Age ≥18 years
- Documented HCM with maximum septal wall thickness ≥15 mm or ≥13 mm with family history of HCM (determined by a core echo laboratory)
- Severe symptoms despite maximally-tolerated medical therapy
  - NYHA functional Class III/IV or Class II with exertional syncope or near syncope
  - Maximal medical HCM therapy could include disopyramide and/or combination therapy
- Dynamic LVOT gradient at rest or with provocation (Valsalva maneuver or exercise) ≥50 mmHg
- Documented LV ejection fraction ≥60%
- Must have been referred within the past 12 months for SRT and actively considering scheduling the procedure
  - Patients could elect to proceed to SRT at any time following randomization

Desai M et al. 2021 Sep;239:80-89
Desai MY et al. J Am Coll Cardiol. 2022 Jul 12;80(2):95-108.

Efficacy and Safety Endpoints

ValorHCM

- Composite principal endpoint
  - Patient decision to proceed with SRT
  - Eligibility for SRT according to the 2011 AHA/ACC guidelines
  - SRT status non-evaluable
- Change from baseline in clinical, laboratory and echocardiographic endpoints
  - Resting and provokable LVOT gradient
  - NYHA functional class
  - Kansas City Cardiomyopathy Questionnaire 23-item Clinical Summary Score (KCCQ-23 CCS)
  - N-terminal pro brain natriuretic peptide (NT-proBNP) and Cardiac troponin I
  - LV mass index, Left atrial volume index and Septal E/e'
- Safety endpoints
  - Death, LV ejection fraction <50%, hospitalization for heart failure, and atrial fibrillation or ventricular tachyarrhythmia

Gersh et al. HCM Guidelines. J Am Coll Cardiol. 2011 Dec 13;58(25):e212-60

Results: Baseline Characteristics

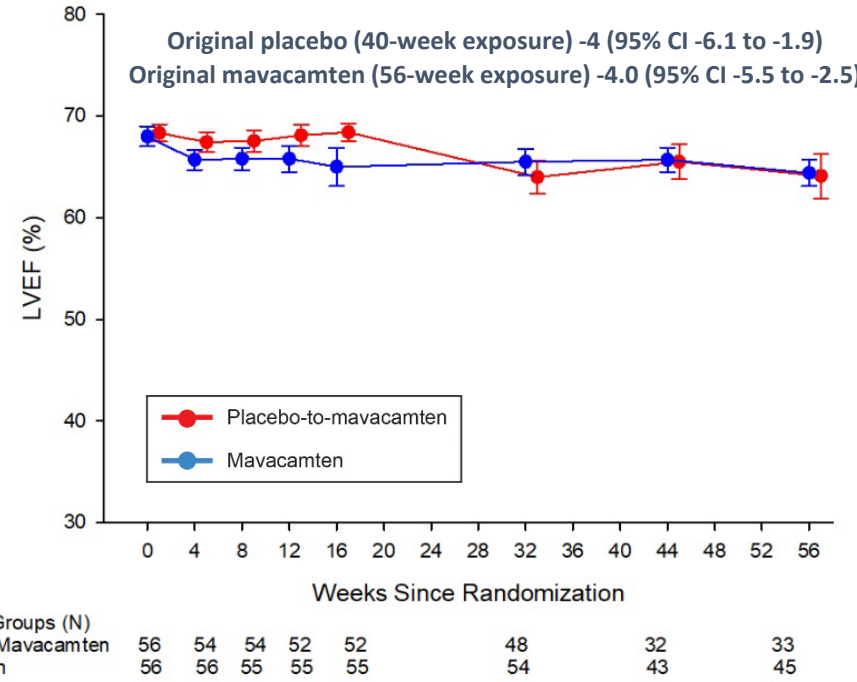
Change in LV filling pressures (E/'e' ratio)	-5.7 (-9.9 to -1.6)	-1.7 (-3.3 to -0.06)	-3.4 (-5.7 to -1.1)	-5.0 (-7.3 to -2.7)
Change in left atrial volume index – ml/m^2	-3.4 (-6.2 to -0.6)	-7.0 (-10.7 to -3.2)	-4.8 (-9.7 to 0.09)	-6.2 (-9.6 to -2.8)

Similar efficacy across both sexes

Selected safety endpoints at Week 56

Characteristic	Placebo-to-mavacamten (40 weeks exposure) N=52	Original mavacamten (56 weeks exposure) N=56	Total mavacamten N=108
Safety endpoints			
Permanent study drug discontinuation a) LVEF <30% b) Two consecutive LVEF measurements of < 50% despite dose reduction to 2.5 mg	 2 (3.8) 1 (1.9)	 0 0	3 (2.8)
One Temporary Interruption for LVEF (>30% to <50%)	2 (3.8)	7 (12.5)	9 (8.3)
Total with ANY LV EF (<50%)	5 (9.6)	7 (12.5)	12 (11.1)
Cardiac death	1 (1.9)*	0	
Heart failure hospitalization	1 (1.9)¥	0	
Selected serious treatment-emergent adverse events			
At least one serious treatment-emergent adverse event	6 (11.5)	4 (7.1)	10 (9.3)
Atrial fibrillation	0	3 (5.4)	3 (2.8)
Congestive heart failure	1 (1.9)	0	1 (0.9)
Ventricular arrhythmia	1 (1.9)	0	1 (0.9)
Drug administration site reaction	2 (3.8)	0	2 (1.9)
COVID-19	0	1 (1.8)	1 (0.9)

LV Ejection fraction



9/12 (75%) patients with LVEF < 50% were asymptomatic and able to resume mavacamten at a lower dose, after temporary interruption

* This patient had a site-reported LV ejection fraction of 30% and mavacamten was discontinued.

¥ This patient was admitted for congestive heart failure with concomitant atrial fibrillation and had a core-lab reported LV ejection fraction < 30%. Mavacamten was permanently discontinued.

Strengths and Limitations

- Composite efficacy endpoint driven by reduction in guideline eligibility for SRT
  - At Week 56, 9 out of 10 patients chose to remain on medical therapy vs. going for SRT
  - Efficacy findings similar in both sexes
  - Echo evidence of sustained disease modification
- Drug efficacy and safety monitored by echo-based LVEF and LVOT gradients, not drug concentrations
  - Successful utilization of site-based echo measurements (after Week 44)
- Need to ascertain long-term safety
  - Effect of mavacamten on long-term arrhythmias and sudden death not assessed
- Current study included predominantly white patients treated at high-volume HCM centers with established SRT programs

Conclusions

Valor HCM

- In obstructive HCM patients with intractable symptoms, referred for SRT, administration of mavacamten, titrated using echocardiography:
  - Significantly reduced eligibility for invasive SRT at 56 weeks
  - Showed treatment benefits for all efficacy endpoints
    - Resting and provoked LVOT gradient, NYHA Class, KCCQ-CSS
    - Reduction in biomarkers (NT ProBNP and troponin I) and significant improvement in echo indices (LV mass index, LA volume index, E/e')
- Given the potential for LV systolic dysfunction, safety and efficacy require continued monitoring

Provides an alternative for medically refractory patients with obstructive HCM, which may obviate the need for SRT in many patients

Longer-term studies evaluating the effect of mavacamten on outcomes are needed

OCTOBER trial

#ESCCongress

OCT-guided or angiography-guided PCI in complex bifurcation lesions

Conclusion

In patients with complex bifurcation lesions, optical coherence tomography (OCT)-guided percutaneous coronary intervention (PCI) is associated with better outcomes after 2 years than angiography-guided PCI.

Impact on clinical practice

The results suggest that routine use of structured OCT guidance during PCI of complex bifurcation lesions should be considered to improve prognosis.

Study objectives

OCTOBER was the first adequately powered clinical trial to examine whether routine use of OCT during PCI of complex bifurcation lesions improves clinical outcomes compared to standard practice with angiographic guidance and optional use of intravascular ultrasound (IVUS) in left main bifurcations.

Study population

Patients with complex bifurcation lesions requiring PCI

Where?

13 European countries

38 heart centres

Who and what?

Primary endpoint

Major adverse cardiac events (MACE), defined as a composite of cardiac death, target lesion myocardial infarction, and ischaemia-driven target lesion revascularisation, after 2 years

Kaplan-Meier estimated hazard ratio 0.70
95% CI 0.50–0.98
p=0.035

Secondary endpoints

Differences in secondary clinical endpoints after 2 years did not reach statistical significance, but the trial was not powered for these endpoints

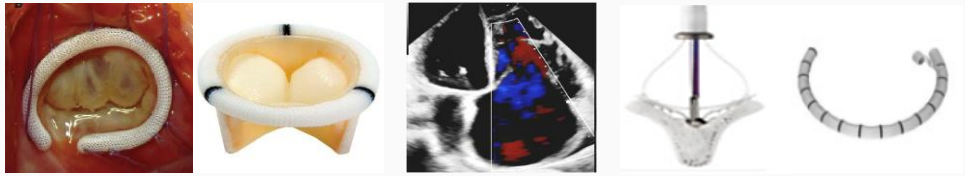
Timing of Intervention in Patients with Severe Tricuspid Regurgitation

Julien DREYFUS and David MESSIKA-ZEITOUN

On behalf of the TRIGISTRY investigators



Disclosure

Julien DREYFUS, MD, PhD

Proctor: Abbott

Dreyfus J et al. EHJ 2023

BACKGROUND

- **Tricuspid regurgitation (TR) = Public health problem**
  - **Highly prevalent in the general population**
  - **Associated with an increased mortality and morbidity**

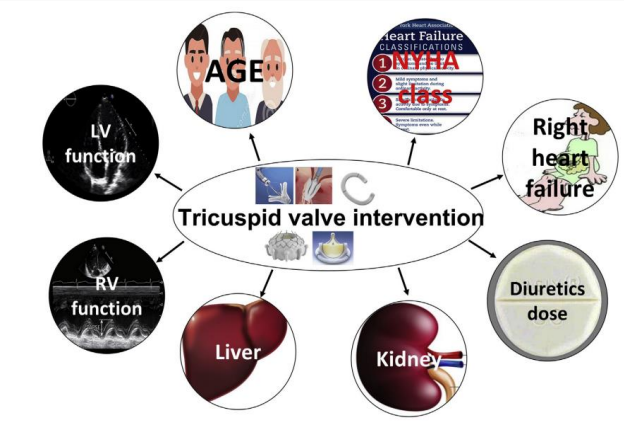
- **Isolated tricuspid valve surgery**
  - **Rarely performed and most patients conservatively managed**
  - **Associated with a high post-operative mortality**
  - **Strong evidence regarding benefit of TR correction is still lacking**

- **Transcatheter intervention**
  - **Represent a less invasive alternative to surgery**
  - **Dominant mode of TR correction in several countries**
  - **TRILUMINATE did not to show any improvement on mortality or heart failure admissions at one year**

Dreyfus J et al. EHJ 2023

BACKGROUND

- **Clinical presentation**
  - Main driver of the post-operative outcome
  - Intervention performed late in the course of the disease → high in-hospital mortality rate / poor outcome
- **TRI-SCORE**
  - Predict in-hospital mortality after isolated tricuspid valve surgery at the individual level
  - Ideally suited to stage TR populations

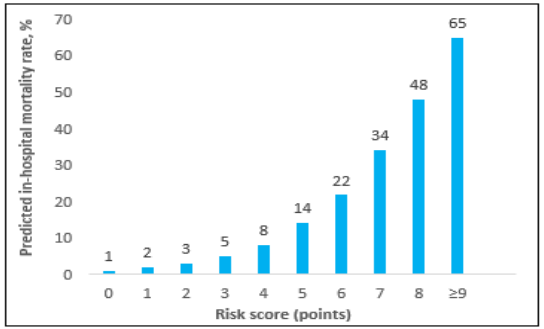


TRI-SCORE

Risk factors and scoring system for in-hospital mortality after isolated tricuspid valve surgery

Risk factors (final model from multivariate analysis)	Scoring
Age ≥ 70 years	1
NYHA functional class III-IV	1
Right-sided heart failure signs	2
Daily dose of furosemide ≥ 125mg	2
Glomerular filtration rate < 30 ml/min	2
Elevated total bilirubin	2
Left ventricular ejection fraction < 60%	1
Moderate/severe right ventricular dysfunction	1
Total	12

Predicted in-hospital mortality rate according to the final risk score model



Messika-Zeitoun D et al. JACC Intv 2022; Dreyfus J et al. EHJ 2021; Dreyfus J et al. EHJ 2023

AIM

To evaluate whether the benefit of an intervention and its modality vary according to TR disease stage as assessed using the TRI-SCORE

Dreyfus J et al. EHJ 2023

TRIGISTRY

- **Multicenter international registry**
  - **Adult patients with severe functional TR on native valve**
  - **Isolated TR (< moderate concomitant left-sided valvular heart disease, no aortic or mitral valve intervention (either surgical or transcatheter) within 3 months)**
  - **TRI-SCORE available (8 mandatory parameters)**
  - **> 30 centers, 10 countries**

Dreyfus J et al. EHJ 2023

Dreyfus J et al. EHJ 2023

METHODS – THE THREE TREATMENT MODALITIES

- **Medical therapy**: no surgical or transcatheter intervention

- **Surgery**: isolated tricuspid valve surgery (repair or replacement) (no concomitant intervention: mitral or aortic valve, coronary artery bypass graft…)

- **Transcatheter valve repair**: multiple repair techniques (no transcatheter valve replacement)

Dreyfus J et al. EHJ 2023

METHODS – TRI-SCORE CATEGORIES

Clinical stage as assessed using the TRI-SCORE:

- Low risk: TRI-SCORE ≤ 3
- Intermediate risk: TRI-SCORE 4-5
- High risk: TRI-SCORE ≥ 6

Dreyfus J et al. EHJ 2023

CONCLUSIONS

1. TRIGISTRY confirms and extends the predictive value of the TRI-SCORE irrespectively of treatment modality at 2 years

2. A tricuspid valve intervention was associated with better survival rates than medical therapy at 2 years in the low and, to a lower extent, intermediate TRI-SCORE categories while survival was similar across groups in the high TRI-SCORE category

3. TRIGISTRY highlighted the prognostic importance of optimal TR correction

Dreyfus J et al. EHJ 2023

PERSPECTIVES

- Our results suggest that, in patients with severe TR, a curative intervention should be considered at an early stage of the disease as assessed by the TRI-SCORE

- TRIGISTRY will guide the design of future randomized controlled trials aiming to formally demonstrate the benefit of tricuspid valve interventions

Dreyfus J et al. EHJ 2023

OCTIVUS trial

OCT- vs. IVUS-Guided PCI

#ESCCongress

Conclusion

Optical coherence tomography (OCT) is non-inferior to intravascular ultrasound (IVUS) for guiding percutaneous coronary intervention (PCI) in patients with diverse coronary artery lesions.

Impact on clinical practice

The results add compelling evidence on the relative efficacy and safety of an OCT-guided strategy compared with an IVUS-guided strategy for PCI.

Study objectives

The OCTIVUS trial was a head-to-head comparison of OCT- and IVUS-guided PCI with regards to clinical outcomes in patients with a broad range of coronary artery lesions.

Study population

Patients

- aged ≥19 years
- undergoing PCI with contemporary drug-eluting stents or drug-coated balloons (only for in-stent restenosis) for significant coronary artery lesions

Where?

South Korea — 9 sites

Who and what?

2,008 patients

randomised 1:1

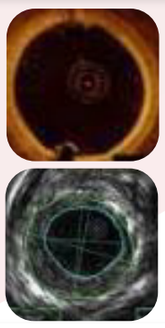
OCT-guided PCI

IVUS-guided PCI

after diagnostic coronary angiography

Primary endpoint

Composite of death from cardiac causes, target vessel myocardial infarction or ischaemia-driven target vessel revascularisation at 1 year, which was powered for noninferiority of the OCT group as compared with the IVUS group (noninferiority margin, 3.1 percentage points)



Rate%

2.5%

3.1%

risk difference, −0.6 percentage points
upper boundary of the one-sided
97.5% CI 0.97; p<0.001 for noninferiority

Safety endpoints

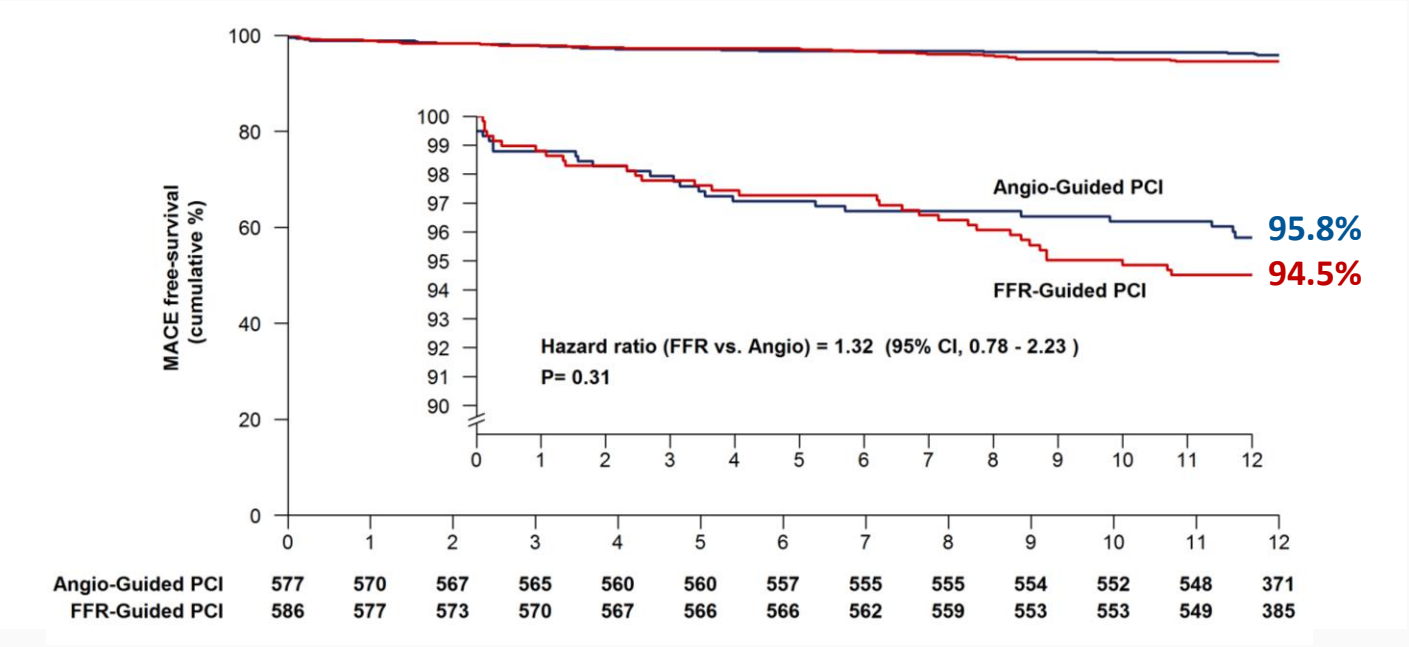
CL, culprit lesion

Primary outcome at 1 Year

FFR-guided strategy was not superior to an angiography-guided strategy for reducing the risk of the composite of death from any cause, non-fatal MI, and unplanned hospitalization leading to urgent revascularization at 1-year



Low event rates of MACE at 1 year: 4.2% / 5.5%

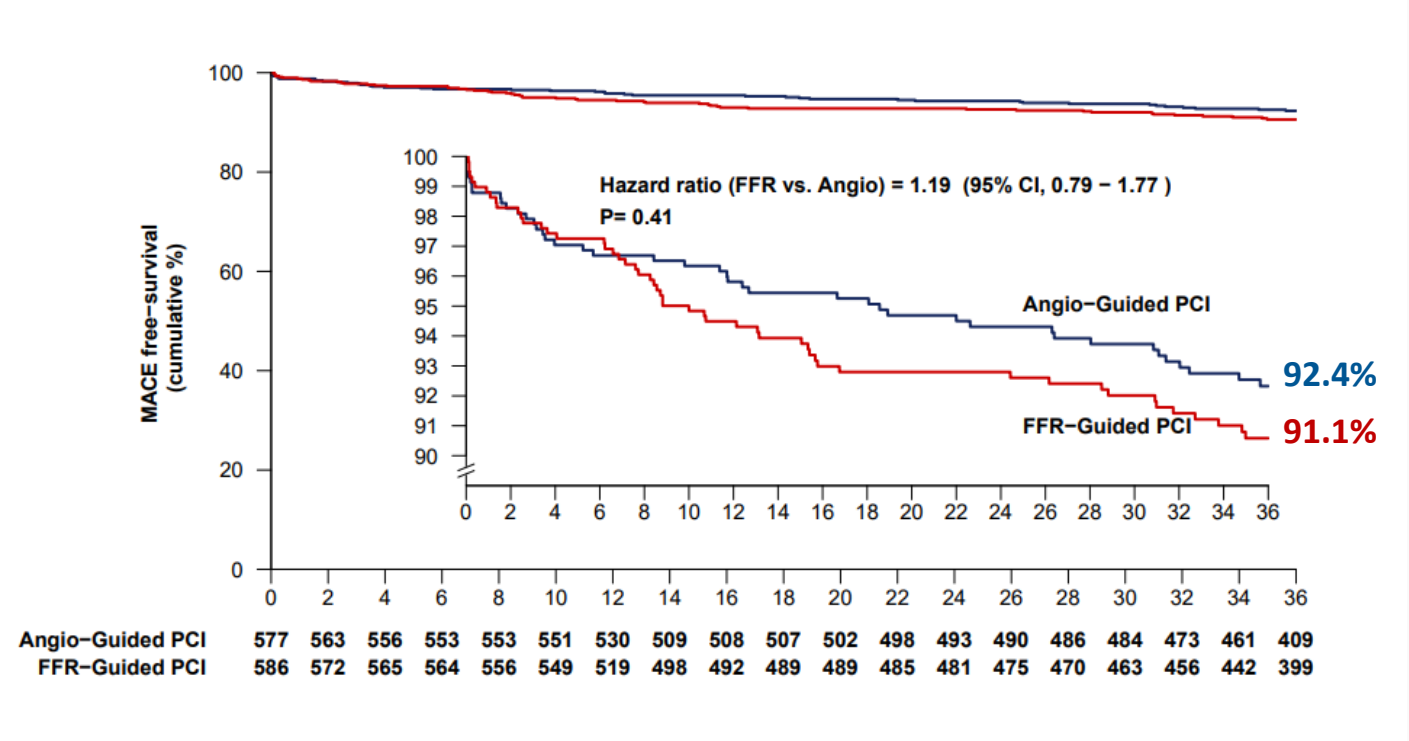
** Major Adverse Cardiac Events (MACE) denotes the composite of all-cause mortality, nonfatal MI, and unplanned hospitalization leading to urgent revascularization*

Puymirat E et al. N Engl J Med 2021

Purpose

- The pre-specified extension phase of the FLOWER MI trial was designed to determine whether a difference in outcomes would be observed beyond the initial one-year follow-up

Primary outcome at 3 Years



Low event rates of MACE at 3 years: 7.6% / 8.9%

** Major Adverse Cardiac Events (MACE) denotes the composite of all-cause mortality, nonfatal MI, and unplanned hospitalization leading to urgent revascularization*

Primary and secondary outcomes at three years

Primary outcome at 3 years	FFR-Guided PCI (n=586)	Angio-Guided PCI (n=577)	HR (95% CI)	P Value
MACE*	8.9 (n=52)	7.6 (n=44)	1.19 (0.79-1.77)	0.41
Death from any cause	3.8 (n=22)	4.0 (n=23)	0.96 (0.53-1.71)	-
Myocardial infarction	3.9 (n=23)	2.4 (n=14)	1.63 (0.84-3.16)	-
Unplanned hospitalization leading to urgent revascularization	3.6 (n=21)	3.1 (n=18)	1.15 (0.61-2.16)	-

** Major Adverse Cardiac Events (MACE) denotes the composite of all-cause mortality, nonfatal MI, and unplanned hospitalization leading to urgent revascularization*

Prespecified clinical outcomes at 3 Years

Secondary outcomes at 3 years	FFR-Guided PCI (n=586)	Angio-Guided PCI (n=577)	HR (95% CI)
Stent thrombosis (%)	0.7	1.2	0.56 (0.16-1.91)
Any revascularization (%)	9.0	7.1	1.30 (0.86-1.95)
Hospitalization for heart failure (%)	1.7	2.6	0.66 (0.29-1.48)
Hospitalization for recurrent ischemia (%)	7.5	5.0	1.54 (0.96-2.46)
Any hospitalization in Cardiology (%)	15.7	12.1	1.34 (0.98-1.83)

Functional status at 3 years	FFR-Guided PCI (n=586)	Angio-Guided PCI (n=577)	HR (95% CI)
Number of anti-anginal medications used *	0.88 ± 0.5	0.9 ± 0.5	0.98 (0.86-1.12)
QALY based on EQ-5D score	0.88 ± 0.14	0.87 ± 0.23	-0.01 (-0.03-0.02)

** Antianginal medications included beta-blockers, calcium antagonists, and nitrates. Rate of means estimated by a negative binomial model*

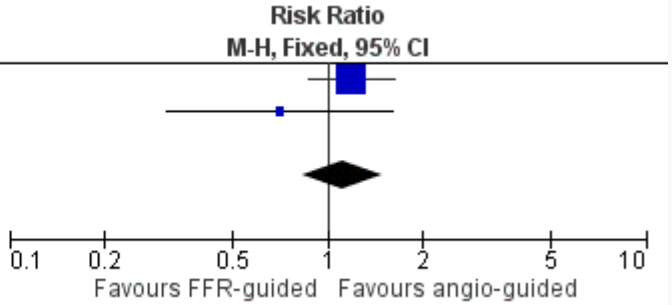
Analysis of FFR-guided versus angio-guided PCI in STEMI patients with multivessel disease: a pooled analysis of the FRAME-AMI and FLOWER-MI trials

Composite outcomes (death, re-MI or any repeat revascularization) in the FRAME-AMI and FLOWER-MI trials

Study or Subgroup	FFR-guided Events	FFR-guided Total	Angio-guided Events	Angio-guided Total	Weight	Risk Ratio M-H, Fixed, 95% CI
FLOWER-MI 2023	76	577	65	586	83.4%	1.19 [0.87, 1.62]
FRAME-AMI 2023	9	131	13	134	16.6%	0.71 [0.31, 1.60]
Total (95% CI)		**708**		**720**	**100.0%**	**1.11 [0.83, 1.48]**
Total events	85		78			

Heterogeneity: Chi² = 1.35, df = 1 (P = 0.25); I² = 26%

Test for overall effect: Z = 0.69 (P = 0.49)



Conclusions

- **In patients presenting with STEMI and MVD treated with multivessel revascularization during the index hospitalization:**
  - Event rates up to 3 years are low
  - FFR-guided PCI of non-infarct-related lesions does not reduce the risk of a composite outcome of death, re-infarction or urgent revascularization at 3-years, as compared with an angiography-guided strategy
  - A pooled analysis using data from the FLOWER-MI and FRAME-AMI trials confirms the lack of benefit of an FFR-guided versus angio-guided strategy in STEMI patients with multivessel disease

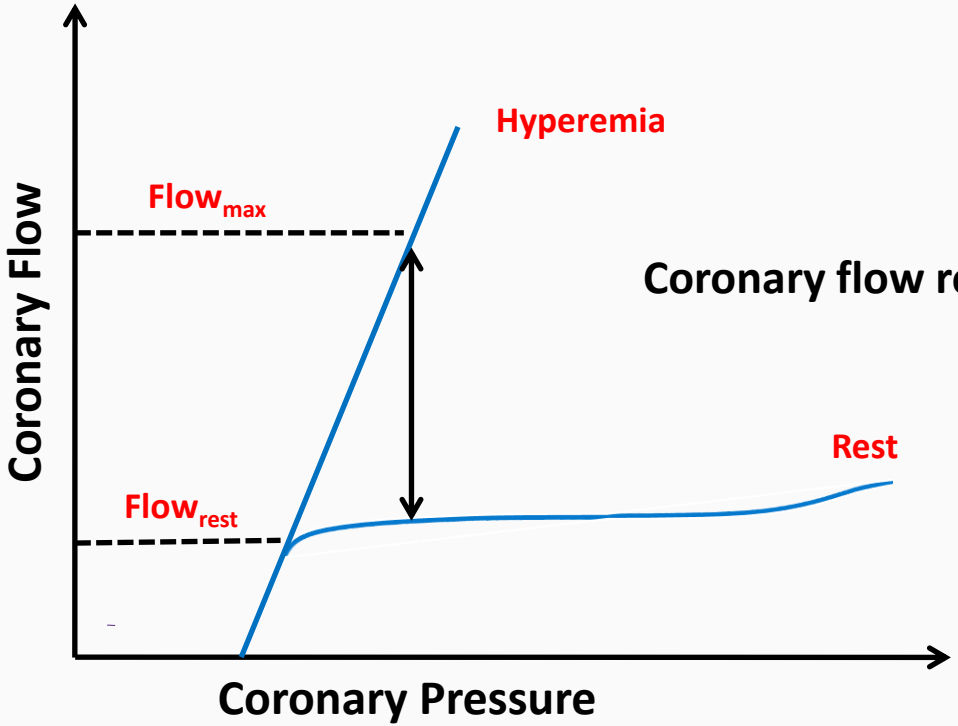
Conflicts of interests

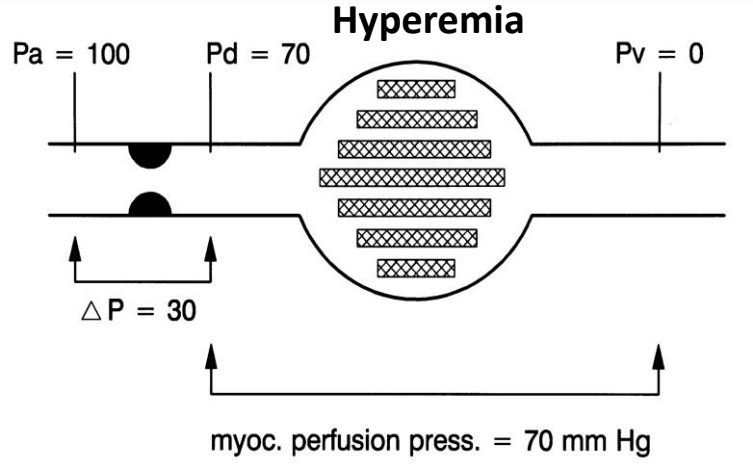
- I do not have any potential conflict of interest to declare

Coronary Flow and Pressure

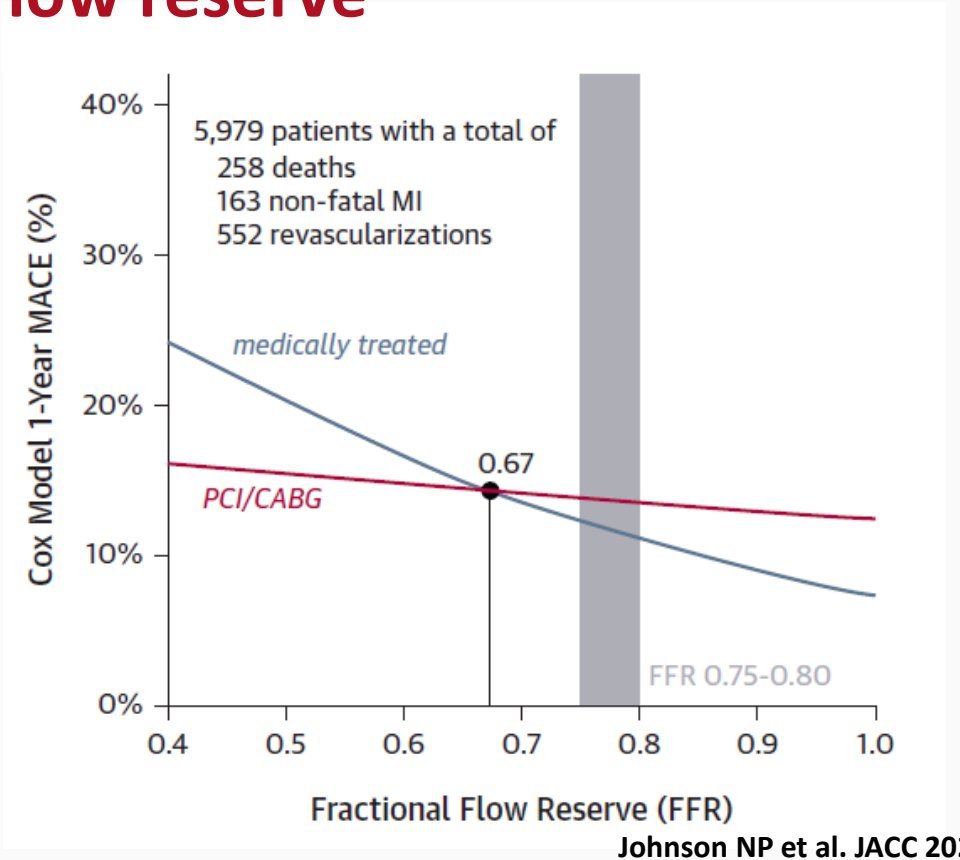


$$\text{Coronary flow reserve} = \frac{Flow_{max}}{Flow_{rest}}$$

Fractional flow reserve



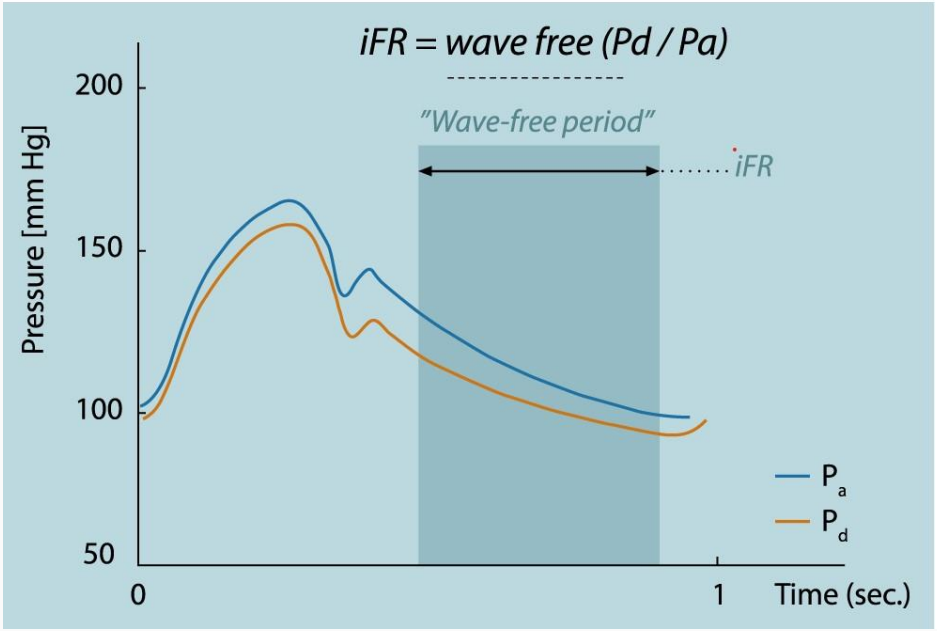
$$FFR = \frac{70\ mmHg}{100\ mmHG} = 0.70$$



Pijls N. et al. Circulation 1995

Johnson NP et al. JACC 2021

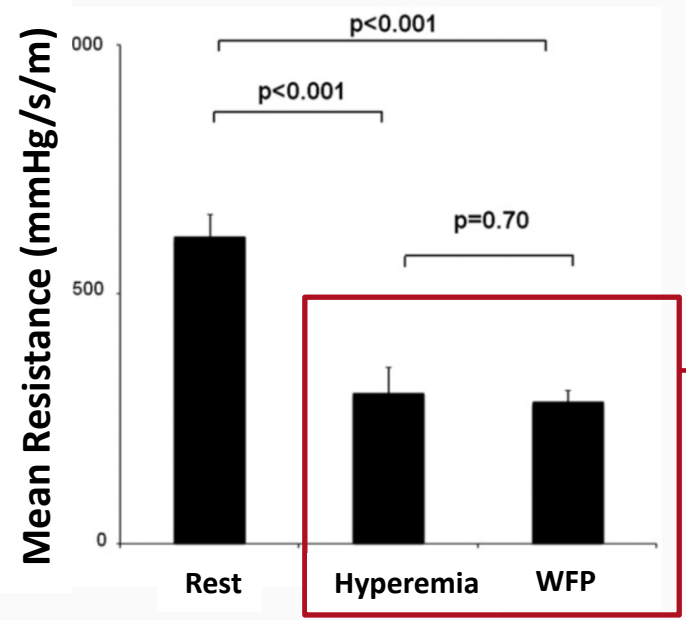
Instantaneous wave-free ratio (iFR)



Minimum resistance during wave free period

$$\text{iFR} = \frac{Pd_{wave\_free}}{Pa_{wave\ free}}$$

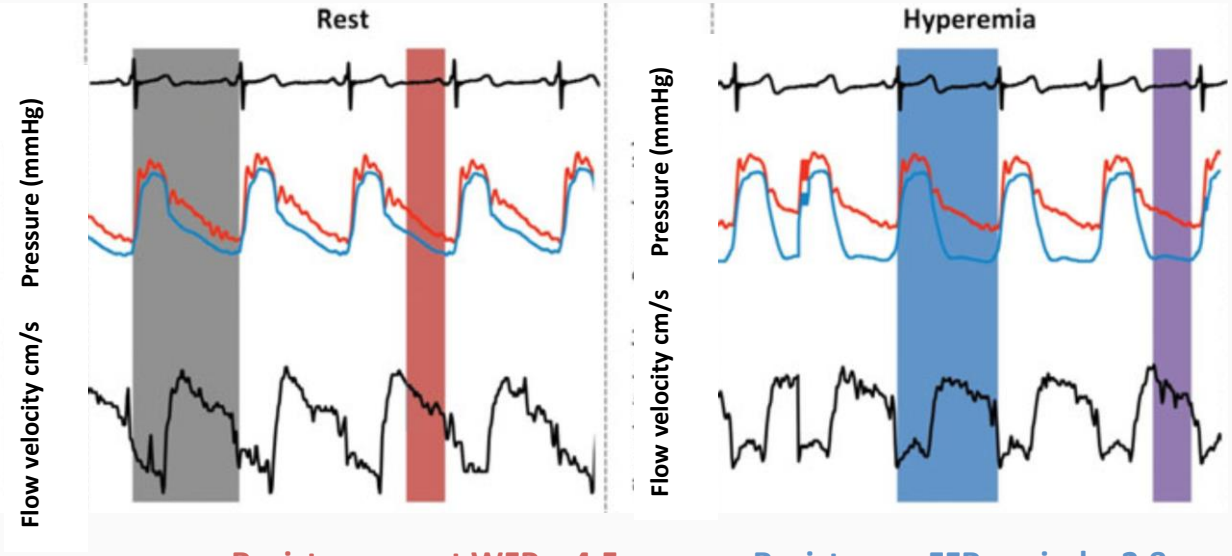
Resistance during the wave-free period (WFP)



”In the first part of this study, we identified the existence of a diastolic interval in which intracoronary resistance rest is equivalent to time-averaged resistance during FFR measurements.”

Sen S, *JACC*. 2012 Apr 10;59(15):1392-402. (Figure 5A and Methods text with *emphasis*)

Resistance in WFP higher than hyperemic resistance



Resistance: rest WFP = 4.5

Resistance: FFR period = 2.8

"A *natural incremental hierarchy exists* between the physiological states assessed: resting whole cycle, *resting wave-free period*, *hyperaemic whole cycle* and hyperaemic wave-free period physiology."

Nijjer SS, *EHJ*. 2016 Jul 7;37(26):2069-80. (Figure 1 portion, p-value and quote from results with *emphasis*)

CENTRAL ILLUSTRATION: Correlations and AUC Values >0.99 for All Resting Pd/Pa Ratios Over Different Periods in Diastole Compared With iFR as the Reference Standard

Functional versus Culprit-only Revascularization in Elderly Patients with Myocardial Infarction and Multivessel Disease

The FIRE trial

Simone Biscaglia, MD

University Hospital of Ferrara (Italy)

on behalf of the FIRE trial Investigators

Background

- Older patients (75+) are poorly represented in conventional randomized controlled trials
- The risk of periprocedural complications is higher and prognostically impactful older patients[1]
- The benefit of complete revascularization in this subset of patients has been recently questioned[2]

1. Biscaglia S, Am Heart J. 2020;229:100-109. 2. Joshi FR, Catheter Cardiovasc Interv. 2021;97:E467-E474.

Research question

To investigate whether, in older patients (75+ years) with MI and multivessel disease, complete revascularization based on coronary physiology is superior to a culprit-only revascularization strategy

Inclusion & Exclusion Criteria

Inclusion

- 75+ years old
- MI (STEMI or NSTEMI)
- Multivessel disease
- Successful PCI of culprit lesion

Exclusion

- Non culprit lesion on left main
- Unclear culprit lesion
- Life expectancy <1 year
- Prior CABG
- Planned surgical revasc

Study Design

All comers, prospective, randomized, multicenter, open-label trial with blinded adjudicated evaluation of outcomes (PROBE).

Pts ≥75 ys hospitalized for MI (STE or NSTE) with indication to invasive management

Multivessel disease at coronary artery angiography

Culprit lesion clearly identifiable and successfully treated

R

Physiology-guided Complete Revascularization

Culprit-only Revascularization

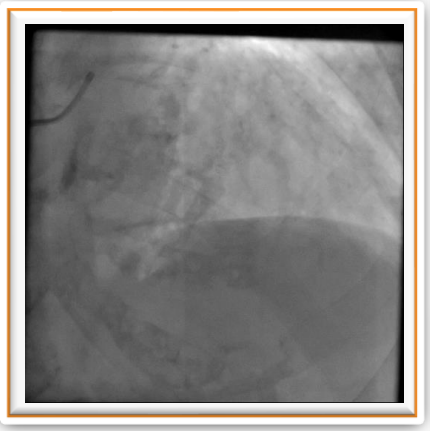
1-, 3-, and 5-year follow-up

Sample Size

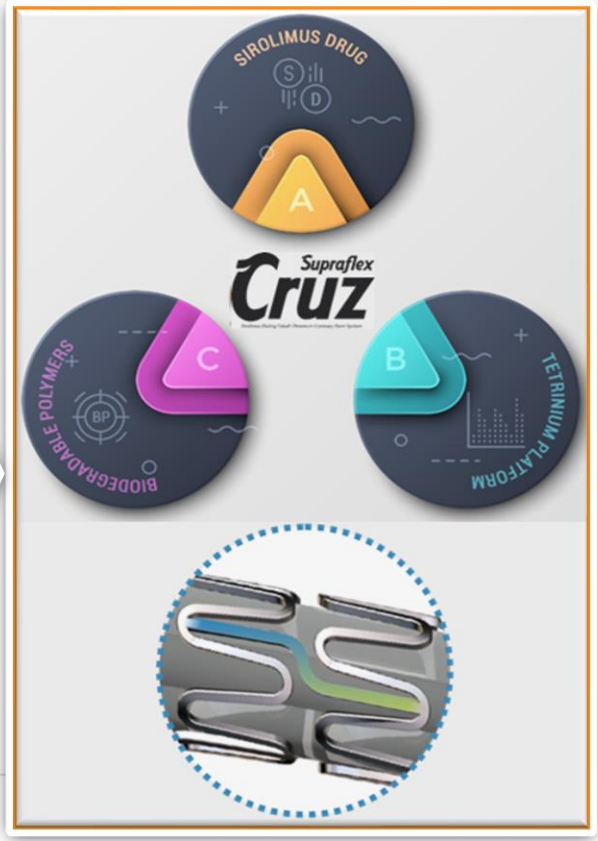
We estimated a conservative 15% rate of the primary endpoint at 1 year in the culprit-only strategy group. Considering that functional assessment should reduce the primary endpoint of at least 30%, 1368 patients are required to have a 80% chance of detecting, as significant at the 5% level, a 30% difference in the primary outcome between the two groups

Coronary Physiology & Stents

- **Non-culprit lesions were assessed with either wire-based FFR, resting index or angiography-derived FFR**
- **Flow-limiting lesions (FFR≤0.80, resting ≤0.89) had to be revascularized with biodegradable-polymer sirolimus ultra-thin stent(s)**



OR



Study Endpoints

Primary endpoint

1-year death, any MI, any stroke, or id-revascularization

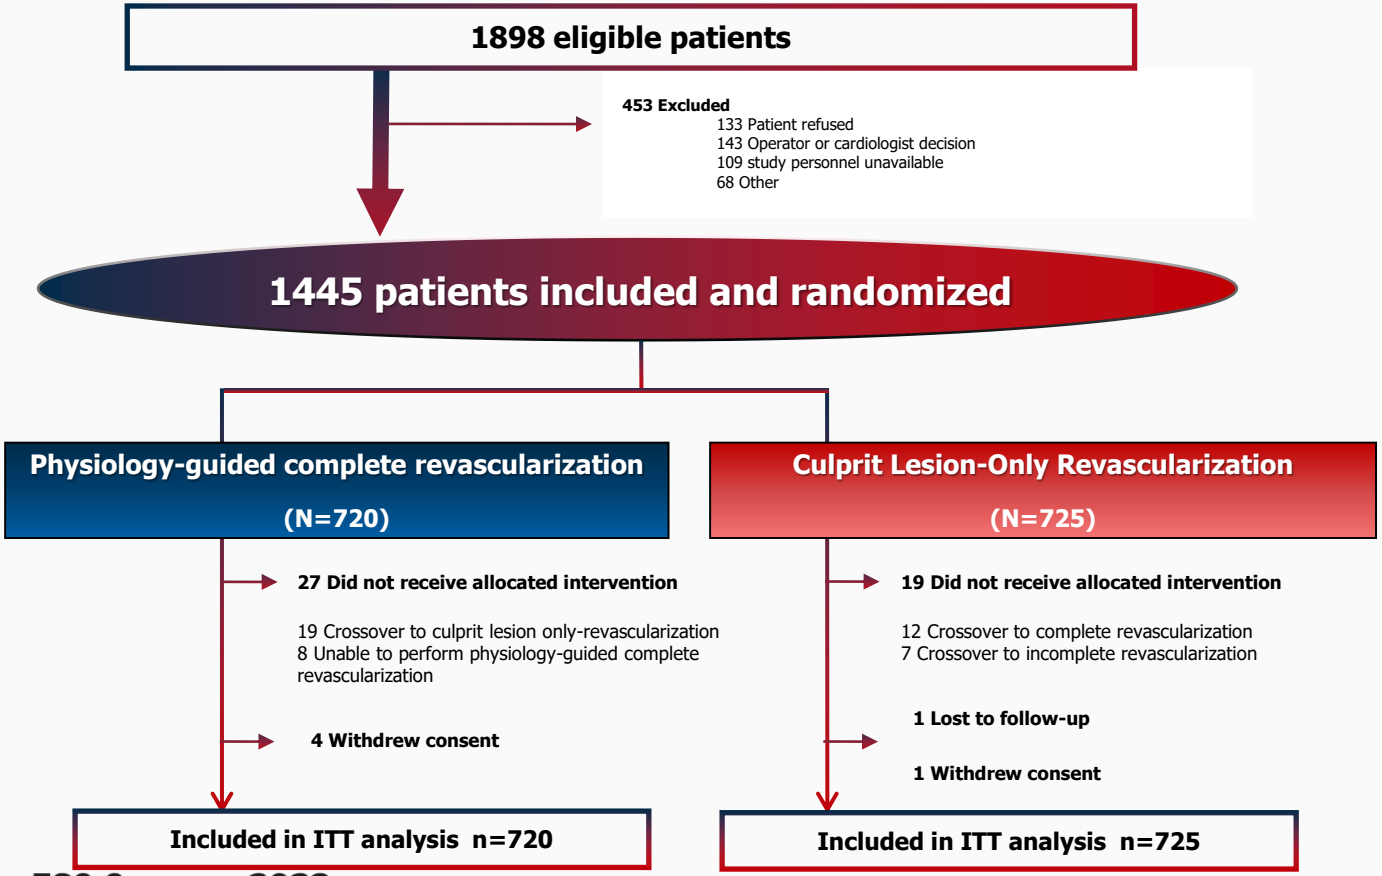
Key secondary endpoint

1-year cardiovascular death or MI

Safety endpoint

1-year CA-AKI, stroke, or BARC type 3-5 bleeding

Study flow-chart



- **76%** of eligible patients enrolled
- **2.6%** crossover from culprit-only
- Follow-up complete in **99.9%** of patients

*Composite of contrast-associated acute kidney injury, stroke, or BARC type 3, 4, or 5 bleeding

Study limitations

- Open label study
- Our results may not apply to:
  - Complete revascularization outside index hospitalization
  - Complete revascularization guided by conventional angiography
  - Patients not treated with biodegradable-polymer sirolimus eluting stent

Conclusions

Among patients aged 75 years or older with MI and multivessel disease, physiology-guided complete revascularization, as compared to a culprit-only revascularization strategy, reduced

- **Composite of death, MI, stroke, or ischemia-driven revasc**
- **Cardiovascular death or MI**

MULTISTARS AMI trial #ESCCongress

Multivessel immediate versus staged revascularisation in STEMI

Conclusion

Immediate multivessel percutaneous coronary intervention (PCI) is non-inferior to staged multivessel PCI for reducing death and ischaemic events in patients with ST-segment elevation myocardial infarction (STEMI) and multivessel coronary artery disease.

Impact on clinical practice

Immediate PCI of non-culprit lesions is as effective and safe as a staged procedure. The results were generally consistent across prespecified key subgroups, particularly among women and men, young and older patients, and patients with or without diabetes.

Study objectives

The MULTISTARS AMI trial investigated whether immediate complete revascularisation at the time of primary PCI was non-inferior to staged (within 19 to 45 days) multivessel PCI among haemodynamically stable patients with STEMI and multivessel coronary artery disease.

Study population

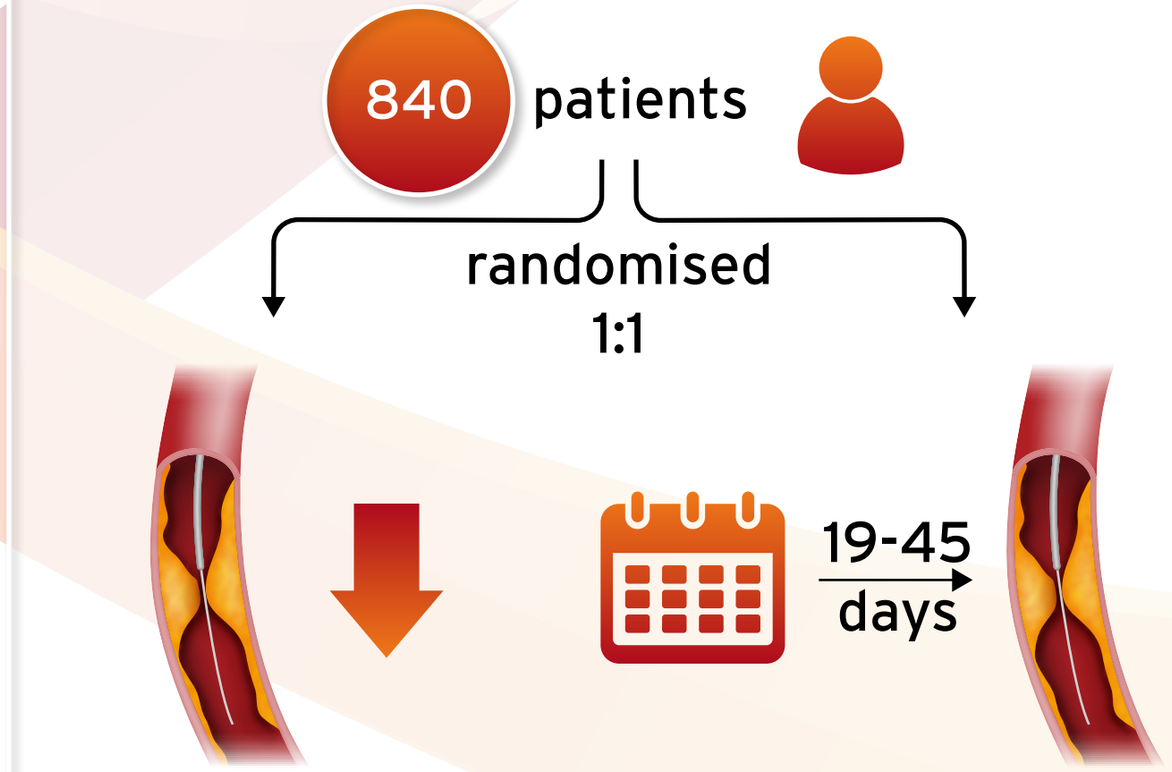
Patients with acute STEMI (presenting within 24 hours of symptom onset) and multivessel coronary artery disease (defined as ≥1 coronary lesion with ≥70% diameter stenosis on coronary angiography based on visual estimation in a non-culprit coronary artery of ≥2.25 mm and ≤5.75 mm in diameter), who were haemodynamically stable after successful primary PCI of the infarct-related coronary artery.

Where?

Europe

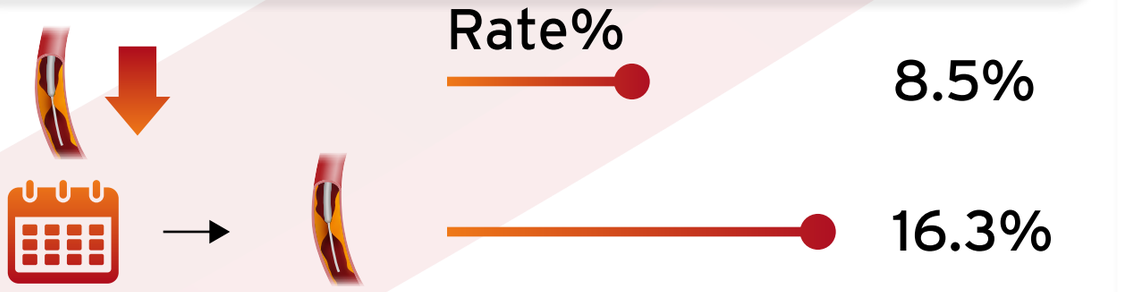
37 sites

Who and what?



Primary endpoint

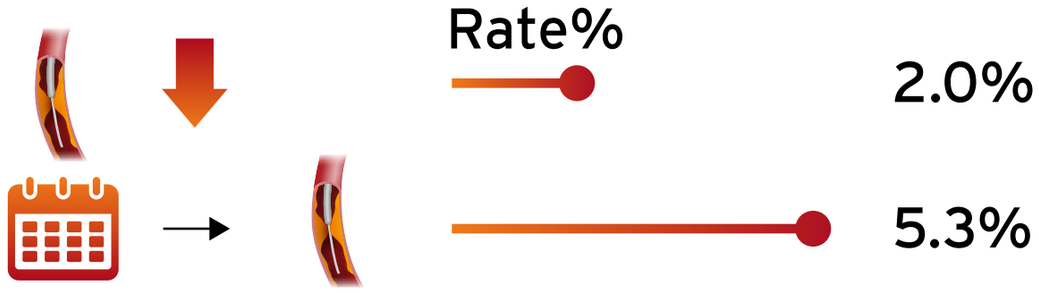
Composite of all-cause death, non-fatal myocardial infarction, stroke, unplanned ischaemia-driven revascularisation, or hospitalisation for heart failure within 1 year after randomisation.



risk ratio 0.52; 95% CI 0.38 to 0.72
p<0.001 for non-inferiority; p<0.001 for superiority

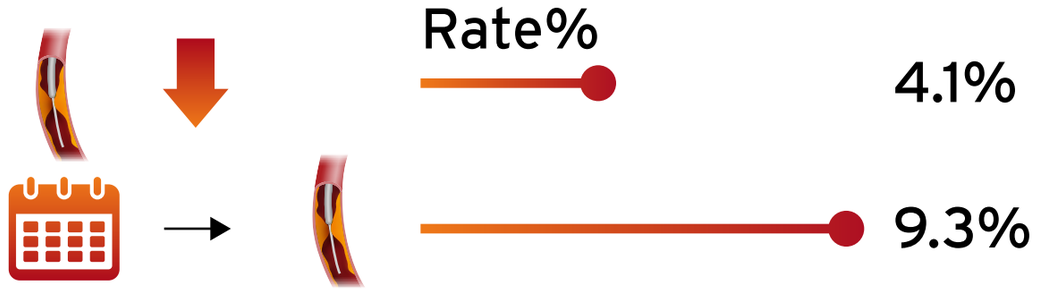
Secondary endpoints

non-fatal myocardial infarction



hazard ratio HR 0.36; 95% CI 0.16 to 0.80

unplanned ischaemia-driven revascularisation



hazard ratio 0.42; 95% CI 0.24 to 0.74

The ARAMIS trial

Anakinra versus Placebo, a Double Blind Randomized Controlled Trial for the Treatment of Acute Myocarditis

Mathieu Kerneis, MD, PhD; Fleur Cohen, MD, PhD; Alain Combes, MD, PhD; Eric Vicaut MD, PhD; Gilles Montalescot, MD, PhD

on behalf of the ARAMIS investigators

Declaration of interest

Dr Mathieu Kerneis reports :

- consulting/lectures fees from Kiniksa, Eligo, Sanofi, Bayer.
- Research grants from Federation Francaise de Cardiologie and French Health Ministry
- Patent for the use of Abatacept in ICI induced myocarditis

All Disclosures are available on www.action-group.org

Study Organization

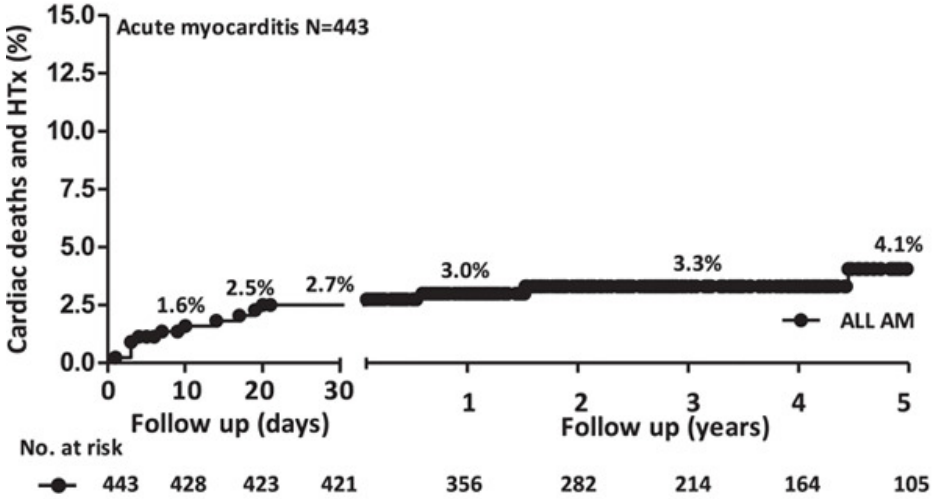
ARAMIS = Independent Academic Trial

- **Academic coordinating center :** Institute of Cardiology – ACTION Group – Pitié Salpétrière Hospital
- **Academic Sponsor :** Assistance Publique-Hopitaux de Paris
- **Academic Global Trial Operations :** URC Lariboisiere, ACTION Group, Paris
- **Academic Funding :** French Ministry of Health (PHRC)
- **Investigation Sites :** 6 academic centers in France
- All analyses were performed by an **independent academic statistician**

Background

Acute Myocarditis

Acute myocarditis (AM) is an **inflammation** of the myocardium that can cause **life-threatening events**



Ammirati et al. Circ 2018

Treatment of Acute Myocarditis

There is no evidence that a treatment targeting inflammation can improve outcome in « virus-negative » myocarditis patients[1]

A strategy of immunomodulation has not been evaluated in acute myocarditis patients with unknown viral replication (without EMB)[2]

Experimental studies and case reports suggest that blockade of the IL1-β pathway could be effective in AM [3,4]

Anakinra, an IL1-R antagonist, used in inflammatory diseases, has an acceptable **safety profile**[5]

[1] Frustaci, *et al.* EHJ 2009 - *TIMIC Trial*

[2] Tschöpe, *et al.* Nat Rev Cardiol 2021

[3] Lim BK, et al. Circ, 2002; [4] Cavalli G et al. Crit Care Med, 2016

[5] Brucato A et al., JAMA, 2016

Goal

To perform a pragmatic trial evaluating the inhibition of the IL-1β immune innate pathway with anakinra, to reduce the risk of clinical events in acute myocarditis patients

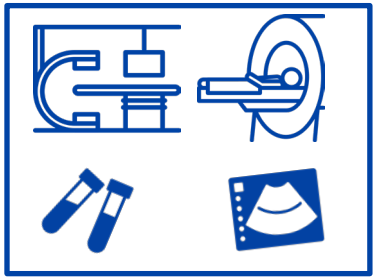
Study design

Study Design of the ARAMIS Trial

Randomized, Double Blind, Multicenter, Phase IIb trial

AM patients

Diagnosis



Within 72 hours

Treatment

R

- Placebo + Standard Therapy
- Anakinra 100mg sc o.d. + Standard Therapy

Follow-up

Number of days alive free of any myocarditis complications

28 days

- **Admission For a Suspected AM**
- **Confirmation of diagnosis and randomization**
- **Hospital Discharge**
- **Primary Endpoint**

Number of days considered for the Primary Endpoint

Inclusion/Exclusion Criteria

Inclusion

Myocarditis was defined as follows :

- Chest Pain
- **AND** modification of the ECG *or* elevated Troponin (at least 1.5 X ULN)
- **AND** CMR Lake Louise Criteria

AND Normal Coronary angiography or CTA in > 40 y/o *or* with CV risk factors

Exclusion

- < 18 y/o or > 65 y/o
- LV assistance
- Mechanical Ventilation
- **Any clinical suspicion of autoimmune, giant cell, eosinophilic, or sarcoidosis related myocarditis**
- Renal Failure
- Anti-TNF, CTC/NSAID use
- Malignancy

Endpoints

Primary Efficacy endpoint :
Number of days alive free of any myocarditis complications

HF requiring hospitalization
Chest Pain requiring medication
LVEF < 50% in TTE
Ventricular arrhythmia, VT or VF

within 28 days post hospitalization

Primary Safety endpoint :
Number of SAEs, including those potentially related to the drug :

Severe infection
ALT/AST > 10x ULN
Neutropenia < 1. 109/L
Renal failure (↑ 50% creat),
Thrombopenia < 50 000 mm3,
BARC> 3, Anaphylactic reaction
100% ↑ of LDL Cholesterol

Sample Size

Superiority trial

anakinra at the approved dosage of 100mg o.d + SOC (betablocker + ACE inhibitor)

vs placebo + SOC

↑ of the number of days free of myocarditis complications

> 1.5 day = clinically meaningful

SD of the 1°EP = 2.3

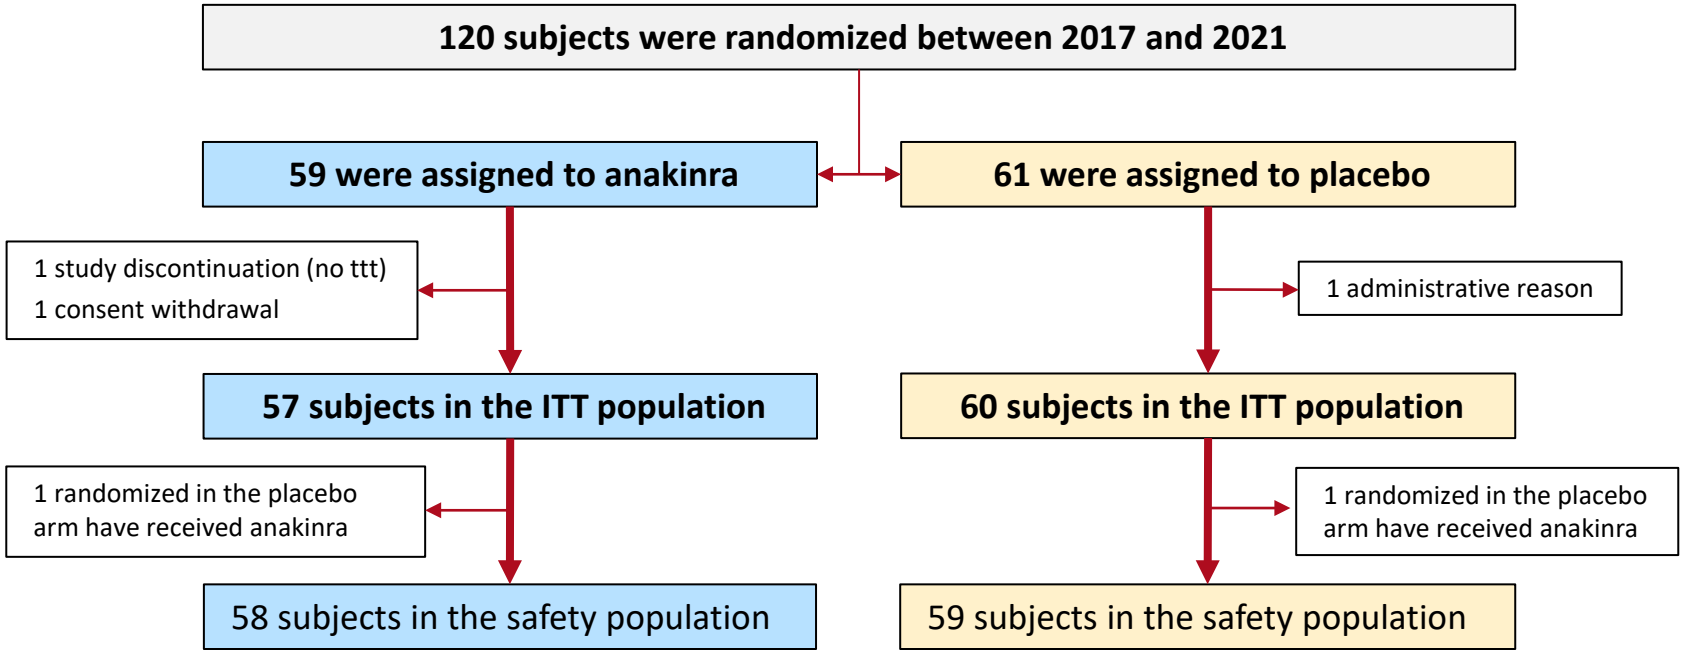
based on the AMPHIBIA registry (NCT04844151)

60 patients in each group

⇒ 80% power to demonstrate a 1.5 day difference

⇒ 5% two-sided significance level

Flow Chart



120 subjects were randomized between 2017 and 2021
59 were assigned to anakinra
61 were assigned to placebo
1 study discontinuation (no ttt)
1 consent withdrawal
1 administrative reason
57 subjects in the ITT population
60 subjects in the ITT population
1 randomized in the placebo arm have received anakinra
1 randomized in the placebo arm have received anakinra
58 subjects in the safety population
59 subjects in the safety population

Patient characteristics

Clinical Presentation (1/2)

	Anakinra N=57	Placebo N=60
Median Age, (Q1;Q3), yrs	28.0 (22.8 ; 38.1)	29.0 (23.2 ; 34.0)
Male — no of patients (%)	52 (91.2%)	50 (83.3%)
Current smoker — no. (%)	30 (52.6%)	30 (50.0%)
Past Medical History		
Prior myocarditis — no. (%)	1 (1.8%)	3 (5.0%)
Recent Bacterial infection— no. (%)	9 (15.8%)	6 (10.0%)
Recent Viral infection — no. (%)	25 (43.9%)	27 (45.0%)
Chest Pain — no.(%)	57 (100%)	60 (100%)
Dyspnea — no. (%)	4 (7.0%)	9 (15.0%)
Cardiogenic shock — no. (%)	1 (1.8%)	0 (0.0%)
Ventricular fibrillation — no. (%)	1 (1.8%)	0 (0.0%)
Conduction disorders — no. (%)	0 (0.0%)	1 (1.7%)
Clinical infectious syndrome — no. (%)	16 (28.1%)	18 (30.0%)

Clinical Presentation (2/2)

	Anakinra N=57	Placebo N=60
Troponin in fold increase of the ULN - Median (Q1;Q3)	**98 (33 ;194)**	**75 (22;217)**
CRP, mg/L - Median (Q1;Q3)	**37 (16;68)**	**23 (14;52)**
(NTpro)BNP, in fold increase of the ULN - Median (Q1;Q3)	0.9 (0.4;1.9)	0.5 (0.3;1.0)

Right or Left BB block — no. (%)	5 (8.8%)	4 (6.7%)
ST-segment elevation — no. (%)	**37 (64.9%)**	**39 (65.0%)**
ST segment depression — no. (%)	5 (8.8%)	7 (11.7%)

Coronary Imaging — no. (%)	48 (84.2%)	47 (78.3)

0 patient with EMB

Non Invasive Imaging

	Anakinra N=57	Placebo N=60
Left ventricular ejection fraction (TTE), %		
Median (Q1;Q3)	60 (50;61)	60 (50;60)
Min, Max	40, 73	35, 66
Ventricular dysfunction with TTE (LVEF<50%) — no. (%)	7 (12.3%)	5 (8.3%)
Regional wall motion abnormalities (TTE) — no. (%)	18 (31.6%)	16 (26.7%)
Left ventricular ejection fraction (MRI), %		
Median (Q1;Q3)	54 (50;60)	55 (52;60)
Min, Max	36, 72	38, 70
Ventricular dysfunction with MRI (LVEF<50%) — no. (%)	13 (22.8%)	10 (16.7%)

Absence of pericardial effusion — no. (%)	48 (85.7%)	47 (78.3%)

Serious Adverse Event potentially related to the drug . ***(Hepatic cytolysis, n=1)***	1	0
Severe Infection	0	0

* Unadjusted Odds Ratio. **Adjusted Odds Ratio for Age and baseline LVEF

Conclusions

ARAMIS, the largest RCT in acute myocarditis, enrolled for the first time an all-comer **acute** myocarditis population diagnosed on **CMR**, mostly at **low risk of events.**

A short administration of anakinra did **not increase the number of days free of myocarditis complications**

There was no safety issue with anakinra administered during the acute phase of myocarditis diagnosed without EMB (**no proof of absence of viral replication**)

Further RCT studies are needed to explore the potential benefit of the anti-inflammatory strategy in acute myocarditis patients at **higher risk of events**

Larger studies are needed to evaluate **prolonged anti inflammatory strategies** in acute myocarditis patients at « low-to-moderate risk » (16% of events at M1)

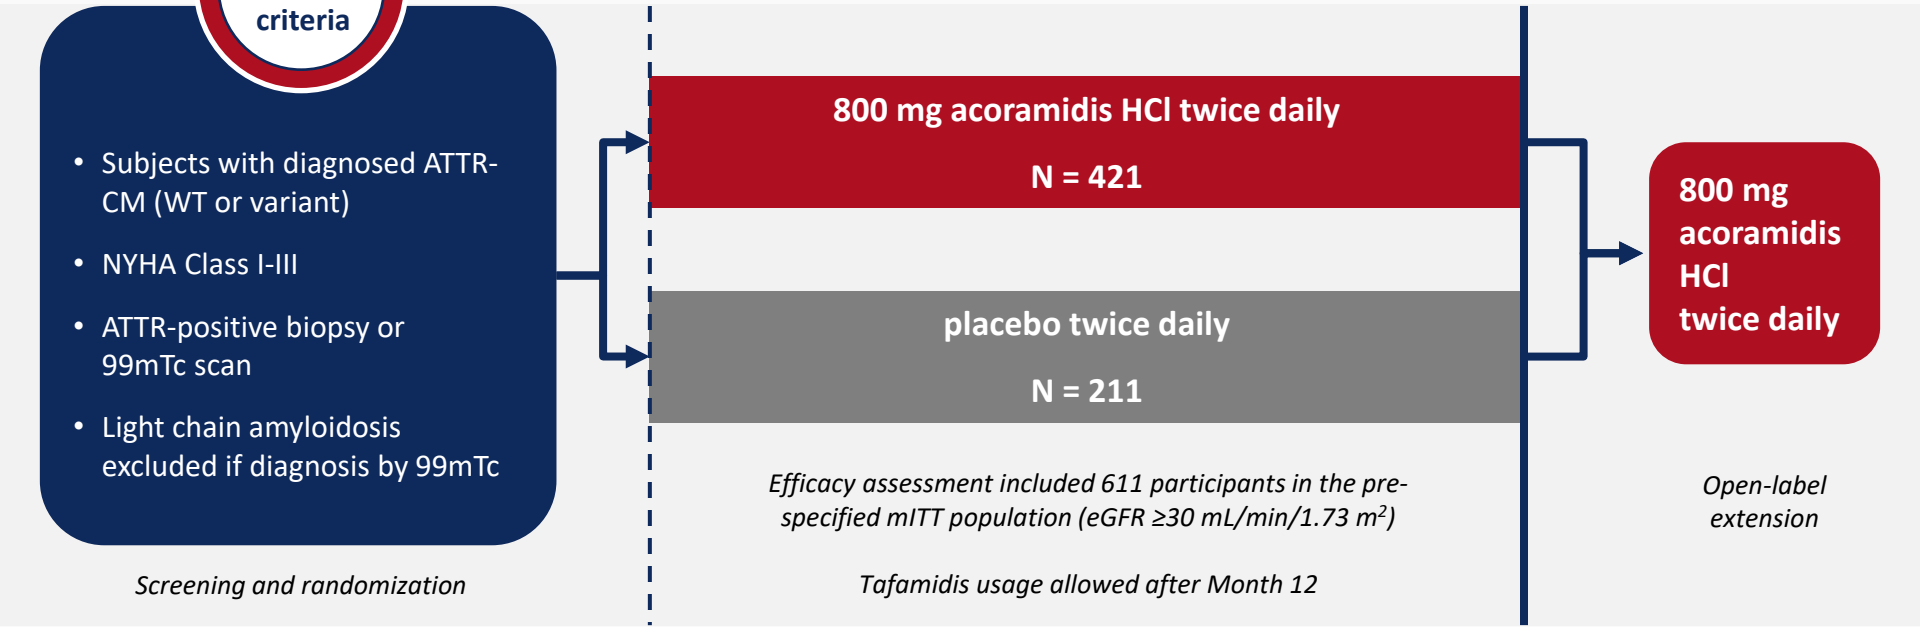
Acoramidis is an investigational molecule. The safety and efficacy have not been fully evaluated by regulatory authorities.

ATTRibute-CM: Study Design

30-month primary endpoint:
Hierarchical analysis consisting of all-cause mortality, cumulative frequency of CVH, change from baseline in NT-proBNP, and change from baseline in 6MWD



6MWD = Six-minute walk distance; NYHA = New York heart association; 99mTc = Technetium labeled pyrophosphate (PYP) or bisphosphonate (e.g., DPD); mITT = Modified intent-to-treat. eGFR = Estimated glomerular filtration rate. ClinicalTrials.gov identifier: NCT03860935.

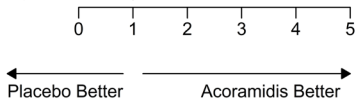
ATTRibute-CM: Baseline Demographic Characteristics

Characteristic	Acoramidis (N=421)	Placebo (N=211)
Age (years), mean (SD)	77.4 (6.5)	77.1 (6.8)
Male sex, n (%)	384 (91.2)	186 (88.2)
ATTRwt-CM, n(%)	380 (90.3)	191 (90.5)
NT-proBNP (pg/mL), median (IQR)	2326 (1332, 4019)	2306 (1128, 3754)
eGFR (mL/min/1.73m^2), mean (SD)	60.9 (18.2)	61.0 (18.7)
TTR (mg/dL), mean (SD)	23.2 (5.6)	23.6 (6.1)
KCCQ-OS, mean (SD)	71.5 (19.4)	70.3 (20.5)
6MWD (m), mean (SD)	361.2 (103.7)	348.4 (93.6)
Concomitant tafamidis use, n (%)*	61 (14.5)	46 (21.8)

ATTRwt-CM = Transthyretin amyloidosis wild-type cardiomyopathy; NT-proBNP = N-terminal pro-B-type natriuretic peptide; IQR = interquartile range; TTR = transthyretin; KCCQ-OS = Kansas City cardiomyopathy questionnaire overall summary score.
*Tafamidis usage allowed after Month 12.

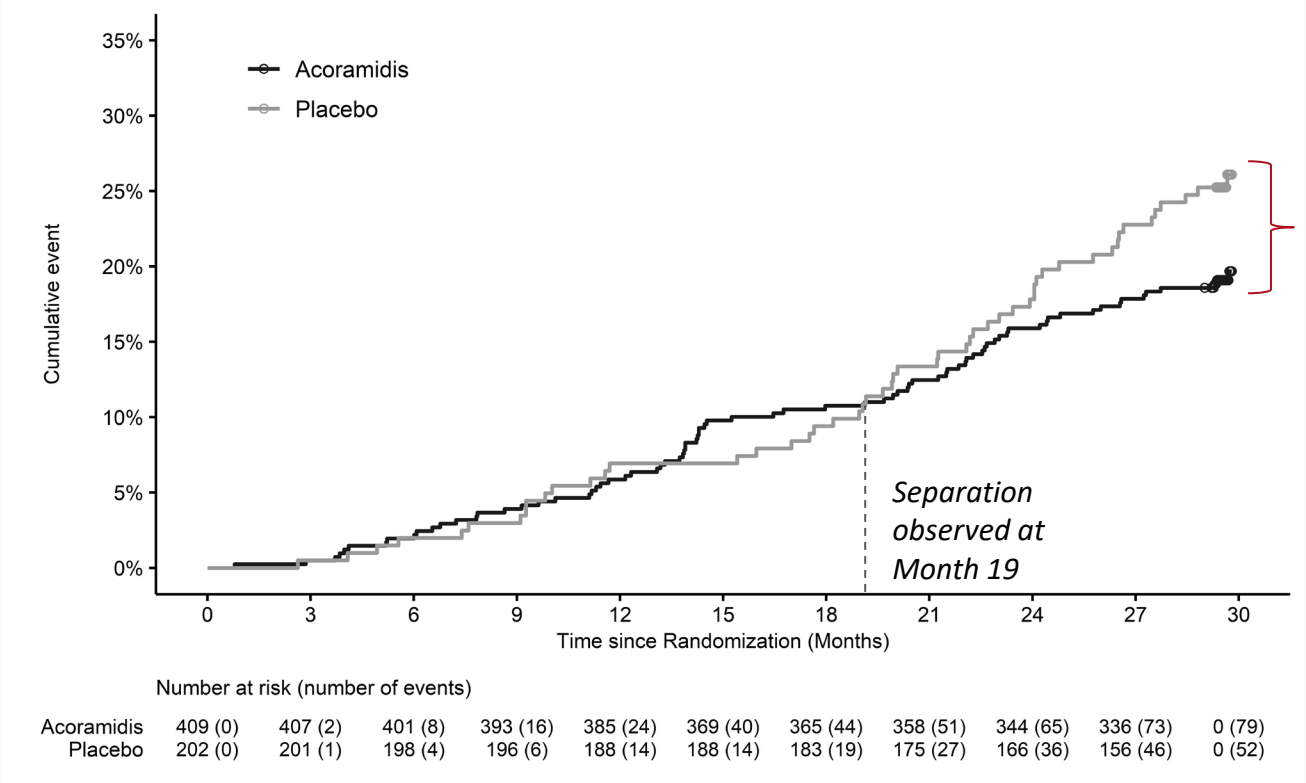
ATTRibute-CM: Primary Outcome Overall and by Subgroups

Subgroup	No. of Patients	Win Ratio [95% CI]	FS test P-value
Overall	611(100.0)	1.772 [1.417, 2.217]	<0.0001
ATTR-CM Genotype			
ATTRm-CM	59(9.7)	2.529 [1.303, 4.911]	0.0061
ATTRwt-CM	552(90.3)	1.756 [1.396, 2.208]	<0.0001
NT-proBNP (pg/mL)			
<= 3000	401(65.6)	1.787 [1.373, 2.325]	<0.0001
> 3000	210(34.4)	1.678 [1.160, 2.426]	0.0060
eGFR (mL/min/1.73m2)			
< 45	94(15.4)	1.410 [0.849, 2.341]	0.1841
>= 45	517(84.6)	1.797 [1.452, 2.226]	<0.0001
Age (years)			
< 78	299(48.9)	2.052 [1.489, 2.829]	<0.0001
>= 78	312(51.1)	1.499 [1.098, 2.045]	0.0107
NYHA Class			
I, II	512(83.8)	1.892 [1.479, 2.419]	<0.0001
III	99(16.2)	1.150 [0.652, 2.030]	0.6292



FS = Finkelstein-Schoenfeld; CI = Confidence interval.

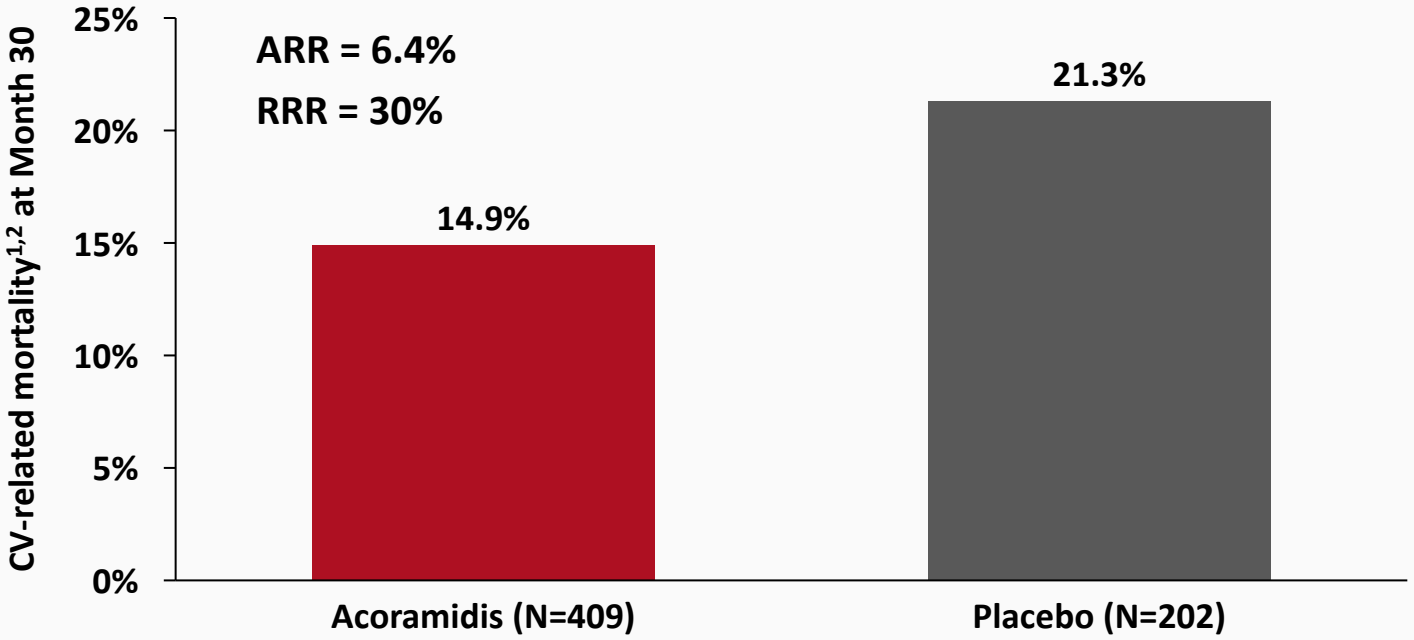
ATTRibute-CM: All-Cause Mortality



ARR = Absolute risk reduction; RRR = Relative risk reduction.

All-cause mortality includes heart transplant, implantation of cardiac mechanical assist device, and all-cause death.

ATTRibute-CM: Cardiovascular-Related Mortality



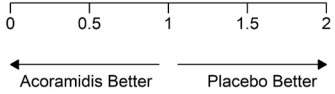
CV-related: Cardiovascular-related.

[1]Heart transplant and implantation of cardiac mechanical assistance device (CMAD) were treated as death for this analysis. N =1 heart transplant & N = 1 CMAD implantation in placebo group.

[2]CV-related mortality includes all adjudicated CV-related and undetermined cause of death.

ATTRibute-CM: Frequency of CVH; P<0.0001 on overall analysis

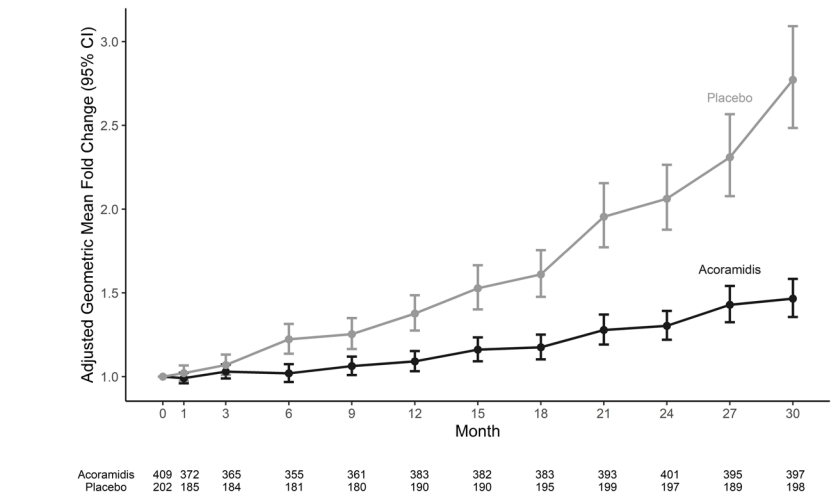
Subgroup	No. of Patients	Relative Risk [95% CI]
Overall	611(100.0)	0.496 [0.355, 0.695]
ATTR-CM Genotype		
ATTRm-CM	59(9.7)	0.377 [0.139, 1.027]
ATTRwt-CM	552(90.3)	0.514 [0.360, 0.734]
NT-proBNP (pg/mL)		
<= 3000	401(65.6)	0.456 [0.299, 0.695]
> 3000	210(34.4)	0.576 [0.330, 1.003]
eGFR (mL/min/1.73m2)		
< 45	94(15.4)	0.594 [0.250, 1.415]
>= 45	517(84.6)	0.481 [0.334, 0.692]
Age (years)		
< 78	299(48.9)	0.437 [0.275, 0.696]
>= 78	312(51.1)	0.576 [0.353, 0.940]
NYHA Class		
I, II	512(83.8)	0.447 [0.310, 0.645]
III	99(16.2)	0.721 [0.313, 1.660]



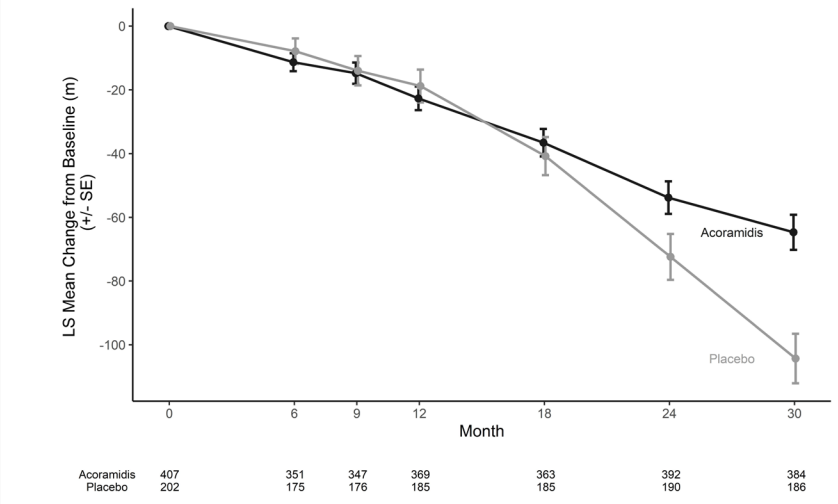
Negative binomial regression with treatment group, stratification factors, and subgroup of interest was used to analyze the cumulative frequency of adjudicated CV-related hospitalization.

ATTRibute-CM: Change from Baseline in NT-proBNP & 6MWD

Change from Baseline in NT-proBNP[1]



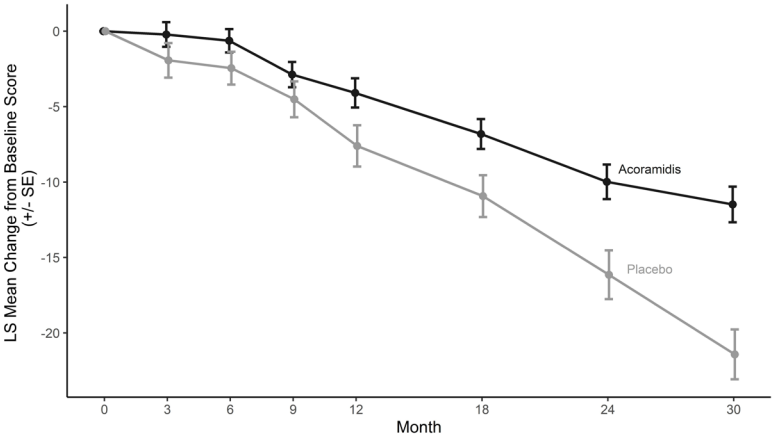
Change from Baseline in 6MWD[1]



[1]Analyzed using mixed effects model with repeated measures. Missing measurements due to early discontinuation imputed using the Jump to Reference method. Missing measurements due to death performed by sampling with replacement from bottom 5% of observed values.

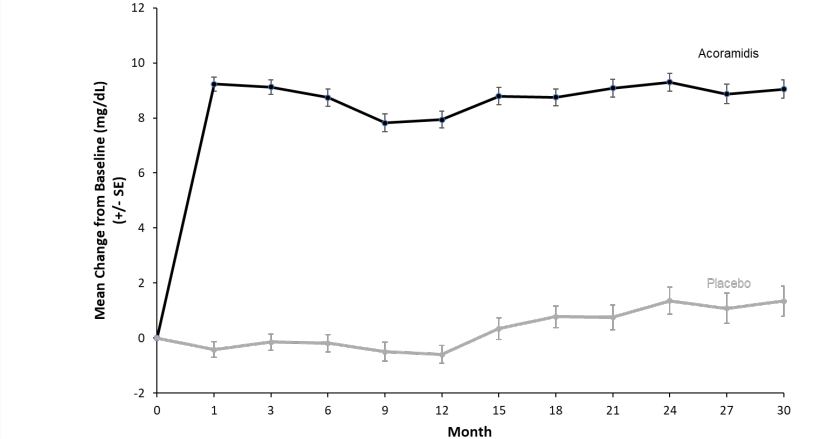
ATTRibute-CM: Change from Baseline in KCCQ-OS & Serum TTR

Change from Baseline in KCCQ-OS[1]



Acoramidis	408	263	389	390	397	404	407	405
Placebo	202	134	192	194	196	199	201	201

Change from Baseline in Serum TTR[2]

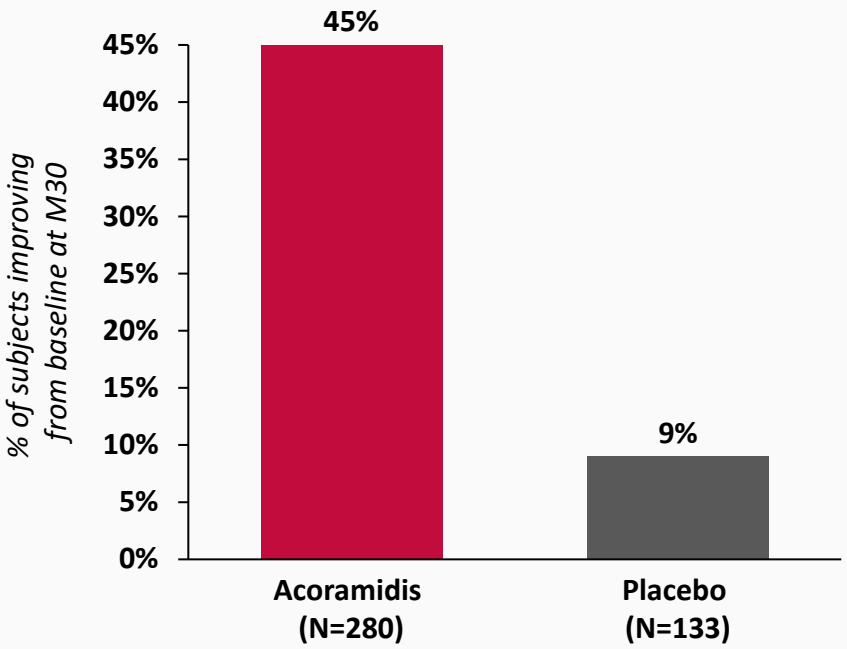


Acoramidis	406	363	348	324	319	328	307	300	294	297	280	283
Placebo	199	178	175	165	162	168	160	160	154	142	128	135

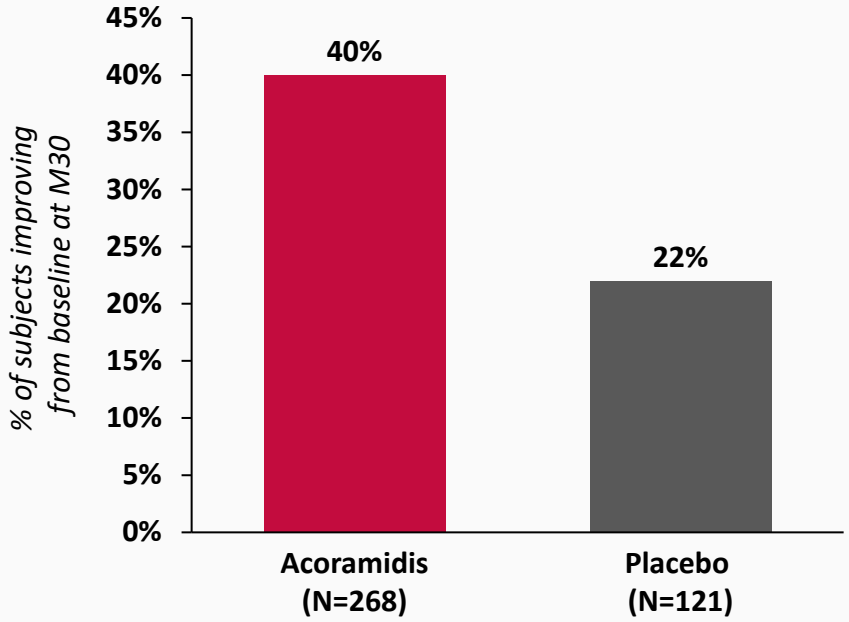
[1]Analyzed using mixed effects model with repeated measures. Missing measurements due to early discontinuation imputed using the Jump to Reference method. Missing measurements due to death performed by sampling with replacement from bottom 5% of observed values. [2]Observed measurements without any imputation. No adjustment was made for early discontinuation for any reason, including death.

ATTRibute-CM: Improvements in Disease Measures

Improvement from baseline in NT-proBNP



Improvement from baseline in 6MWD



mITT population. Improvement is defined as <0 pg/mL change from baseline to month 30 for NT-proBNP; >0 meter change from baseline to month 30 for 6MWD. In both cases, among subjects with both baseline and month 30 values.

ATTRibute-CM: Patient Safety

Subjects with one or more event(s)	Acoramidis N=421 N (%)	Placebo N=211 N (%)
Any treatment-emergent adverse events (TEAEs)	413 (98.1%)	206 (97.6%)
TEAE with fatal outcome	60 (14.3%)	36 (17.1%)
TEAE leading to hospitalization	212 (50.4%)	128 (60.7%)
TEAE leading to study drug discontinuation	39 (9.3%)	18 (8.5%)
Any treatment-emergent serious adverse events (SAEs)	230 (54.6%)	137 (64.9%)
Treatment-emergent SAEs leading to study drug discontinuation	21 (5.0%)	15 (7.1%)
Severe TEAEs[1]	157 (37.3%)	96 (45.5%)

Acoramidis was generally well-tolerated with no findings of potential clinical concern

All Adverse Events (AEs) occurring during the treatment period are considered treatment-emergent adverse events (TEAEs). Serious Adverse Event (SAE) meets seriousness criteria.
[1]Severity as assessed by the investigator.

ATTRibute-CM: Conclusions

- **Primary endpoint analysis (Finkelstein-Schoenfeld hierarchy of ACM, CVH, NT-proBNP, 6MWD) highly statistically significant**
  - Win ratio 1.8; p<0.0001; 58% of win ratio ties broken by ACM + CVH
- **Consistent treatment effect across secondary endpoints**
  - Better preservation of functional capacity (6MWD) and QoL (KCCQ-OS)
  - Reduced progressive increase in NT-proBNP; 45% of patients improved
- **81% survival rate on acoramidis approaches survival rate in age-matched US database (~85%)[1,2]**
- **0.29 mean annual CVH frequency on acoramidis approaches annual hospitalization rate observed in broader US Medicare population (~0.26)[3]**
- **Reassuring safety profile**

Bioflow-DAPT

Biodegradable-Polymer or Durable-Polymer Stents in Patients at High Bleeding Risk

A randomized, open-label clinical trial to assess the safety of HBR patients undergoing PCI with implantation of a drug-eluting stent and treated with DAPT for 1 month

M. Valgimigli, MD, PhD
Cardiocentro Ticino Institute
University of the Italian Switzerland
Lugano, Switzerland

@vlgmrc

25 August 2023

Declaration conflict of interest

- Grants and/or personal fees from Astra Zeneca, Terumo, Alvimedica/CID, Abbott Vascular, Daiichi Sankyo, Bayer, CoreFLOW, Idorsia Pharmaceuticals-Ltd, Universität Basel Department Klinische Forschung, Vifor, Bristol-Myers-Squib SA, Biotronik, Boston scientific, Medtronic, Vesalio, Novartis, Chiesi, PhaseBio.

Background

- Randomized and non-randomized studies have shown that 1-month DAPT after PCI reduces bleeding without compromising safety compared with more prolonged treatment durations in patients at high bleeding risk (HBR).[1,2]

- However, there is limited information on the comparative efficacy and safety of different stent platforms in HBR patients undergoing an abbreviated DAPT duration after PCI.

- Onyx ONE compared 2 drug-eluting stent platforms in patients at high bleeding risk undergoing 1 month of DAPT and showed that durable-polymer zotarolimus-coated stents were associated with non-inferior outcomes to polymer-free umirolimus-coated stents.[3]

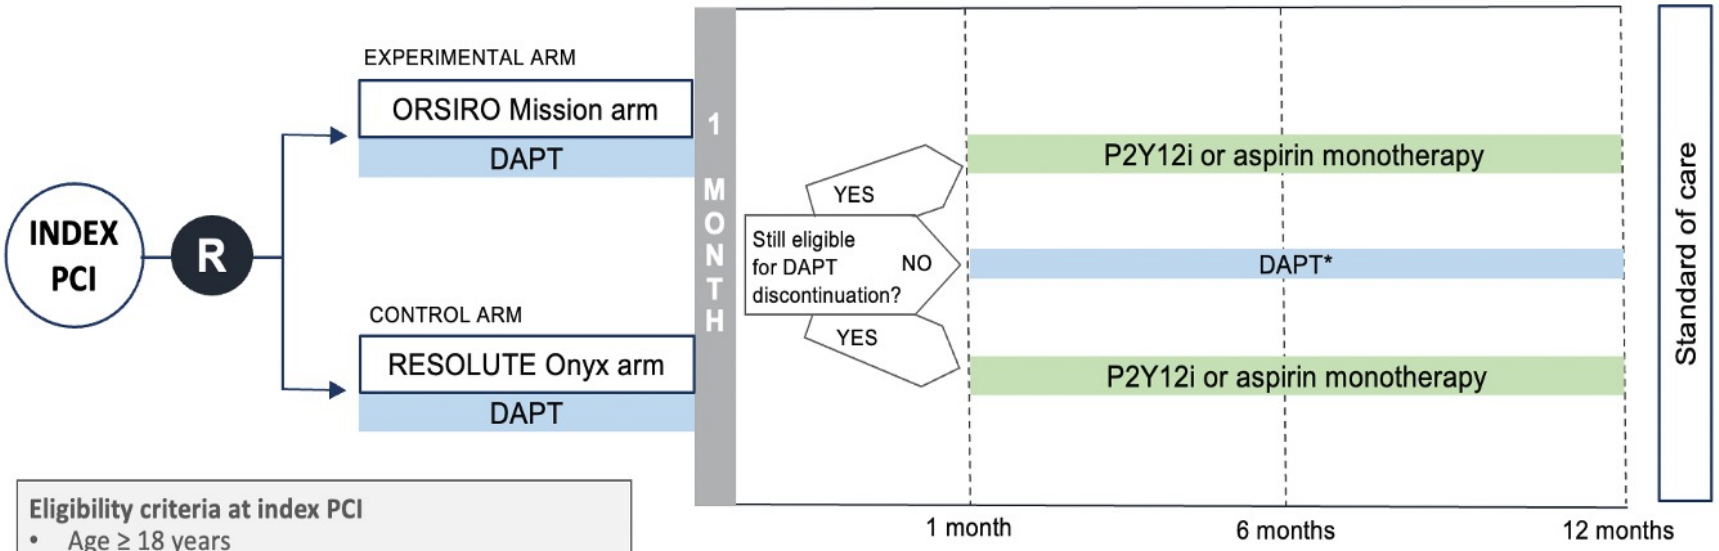
Study Design



Eligibility criteria at index PCI

- Age ≥ 18 years
- Acceptable candidate for treatment with DES
- Patient at HBR
- Able to comply with all protocol and follow-up requirements
- Eligible for 1-month DAPT

12-month primary endpoint
The composite of cardiac death, myocardial infarction and definite or probable ST

* Subjects will not be excluded from the study but will be assessed at each follow-up visit through 12 months.

High Bleeding Risk Definition (1 or more criteria)

a. ≥ 75 years of age

b. Moderate or severe chronic kidney disease or failure

c. Advanced liver disease

d. Cancer diagnosed or treated within the previous 12 months or actively treated

e. Anemia with hemoglobin < 11.0 g/dL or requiring transfusion within 4 weeks before randomization

f. Baseline thrombocytopenia

g. History of stroke, previous intracerebral hemorrhage (ICH) or presence of a brain arteriovenous malformation

h. History of hospitalization for bleeding within previous 12 months

i. Chronic clinically significant bleeding diathesis

j. Clinical indication for chronic or lifelong oral anticoagulation (OAC)

k. Clinical indication for chronic steroid or oral non-steroidal anti-inflammatory drug(s) other than aspirin

l. Non-deferrable major surgery on DAPT

m. Recent major surgery or major trauma within 30 days before PCI

n. PRECISE DAPT score ≥ 25

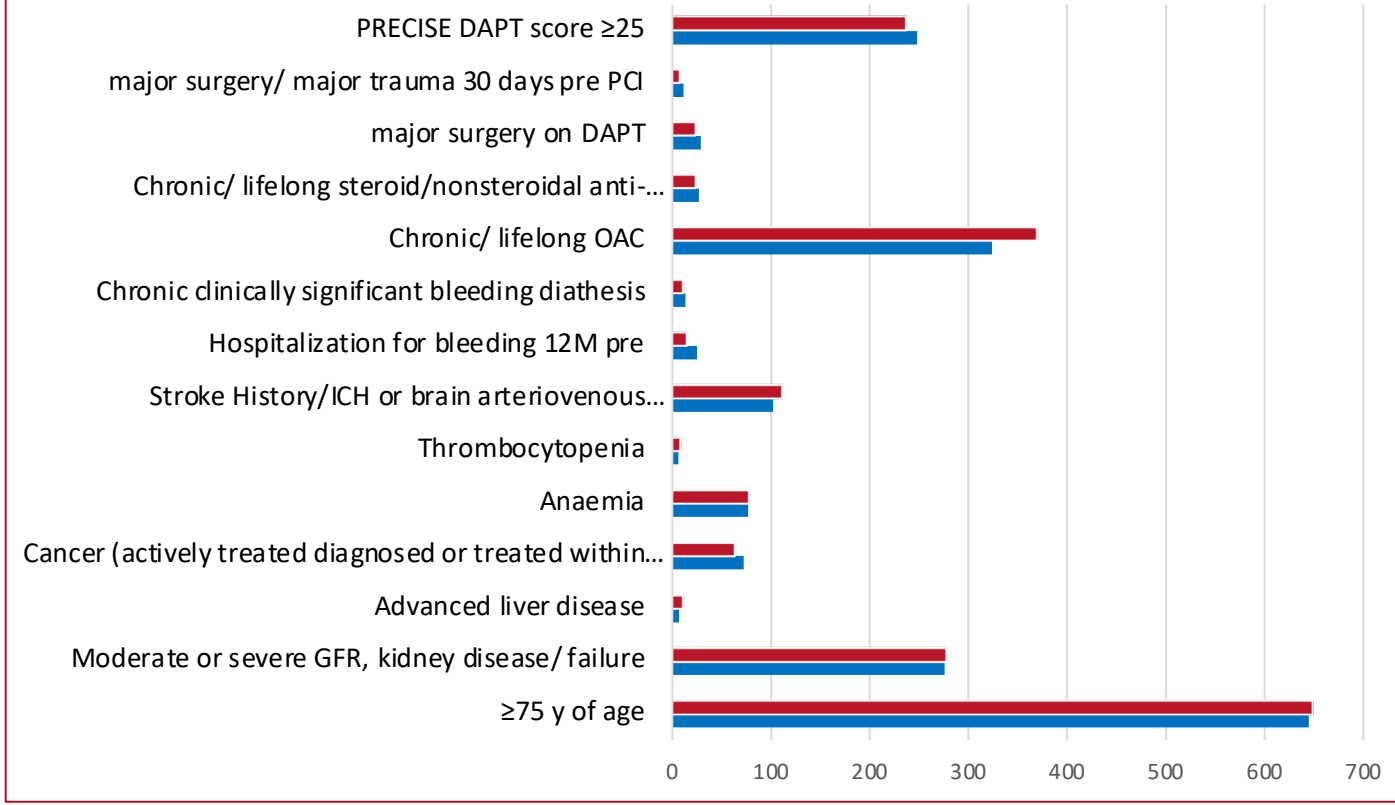
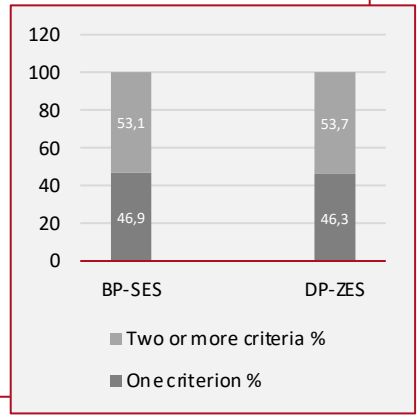
Patient Characteristics (N=1948 pts)

Characteristic	BP-SES (n=969 Patients)	DP-ZES (n=979 Patients)
Age [years] Mean ± SD	76.0 ± 8.5	75.6 ± 8.2
Male	658 (67.9)	679 (69.4)
Renal disease	321 (33.1)	323 (33.0)
Hepatic disease	30 (3.1)	32 (3.3)
Respiratory disease	142 (14.7)	136 (13.9)
Hypertension	787 (81.2)	804 (82.1)
Hypercholesterolemia	659 (68.0)	678 (69.3)
Diabetes	301 (31.1)	311 (31.8)
Smoking History		
Ex-smoker	317 (32.7)	324 (33.1)
Current smoker	131 (13.5)	120 (12.3)
Congestive heart failure	215 (22.2)	202 (20.6)
Oral anticoagulant	324 (33.4)	369 (37.8)
Stable angina	477 (49.6)	495 (50.9)
Silent ischemia	190 (19.8)	197 (20.3)
Non–ST-elevation myocardial infarction	182 (19.0)	180 (18.5)
ST-elevation myocardial infarction	16 (1.7)	17 (1.7)

High-Bleeding Risk Criteria





Procedural Characteristics at Patient Level (1)

Characteristic	Biodegradable-Polymer Stent (n=969 Patients)	Zotarolimus-Eluting Stent (n=979 Patients)
Access[b], no. (%)		
Radial	815 (84.1)	834 (85.2)
Femoral	137 (14.1)	130 (13.3)
Brachial	10 (1.0)	9 (0.9)
Lesion location[c], no. (%) (at least 1 lesion)		
Left main	45 (3.7)	38 (3.9)
Left anterior descending	529 (55.2)	541 (55.6)
Left circumflex	270 (28.2)	264 (27.1)
Right coronary artery	310 (32.3)	299 (30.7)
Bypass graft	16 (1.7)	15 (1.5)
At least one B2/C lesion class[c], no. (%)	583 (60.9)	614 (63.5)
At least one lesion with moderate or severe calcification‡, no. (%)	339 (35.3)	335 (34.5)
At least one lesion with bifurcation[c], no. (%)	290 (30.2)	308 (31.7)

a Plus–minus values are means±SD.

b Unknown for 7 patients in biodegradable-polymer stent group and 6 patients in the zotarolimus-eluting stent group.

c Unknown for 10 patients in biodegradable-polymer stent group and 6 patients in the zotarolimus-eluting stent group (percentages were calculated using a total of 959 patients in the biodegradable-polymer stent group and 973 patients in the zotarolimus-eluting stent group).

Procedural Characteristics at Patient Level (2)

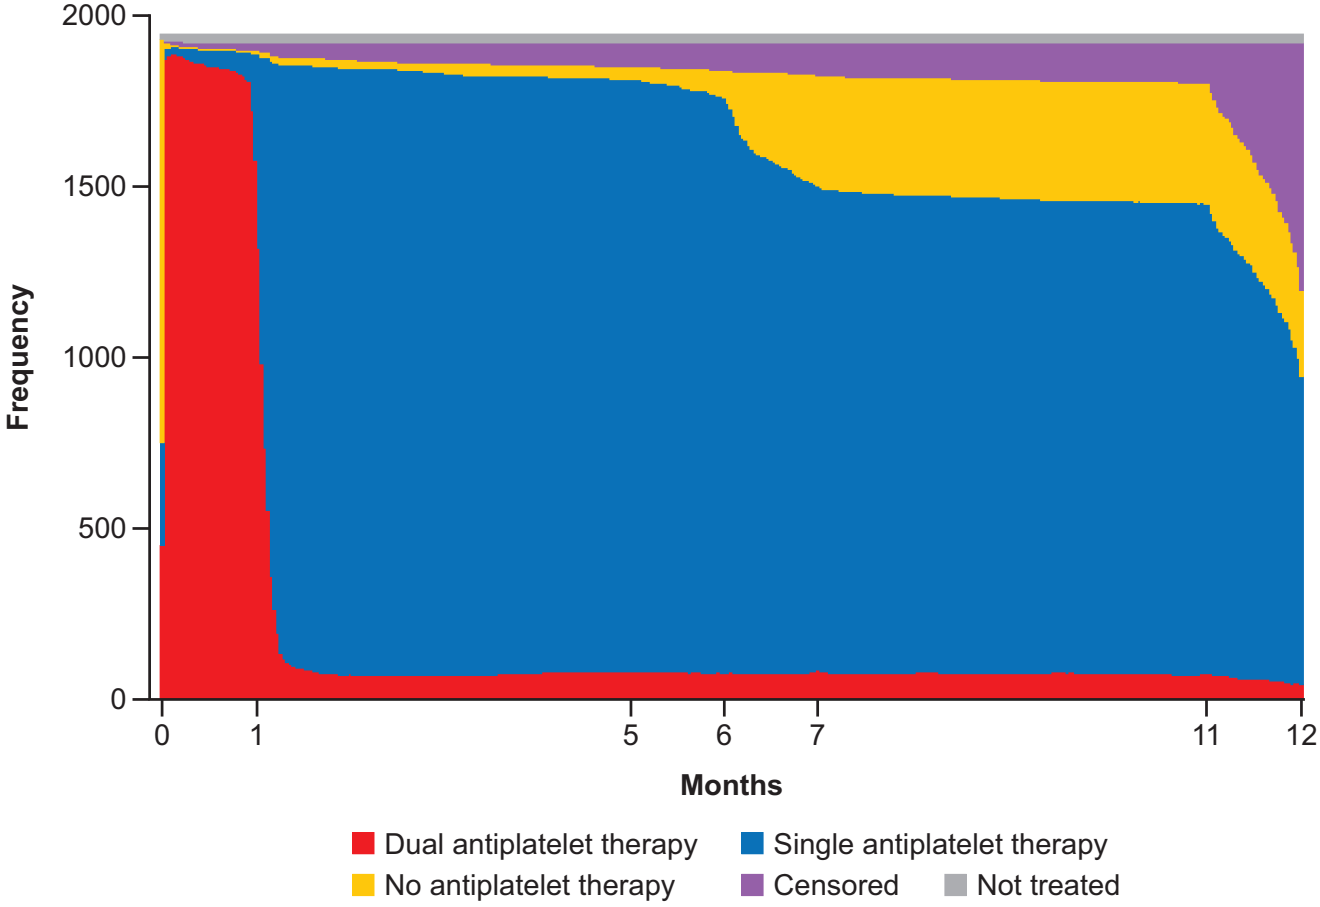
Characteristic	Biodegradable-Polymer Stent (n=969 Patients)	Zotarolimus-Eluting Stent (n=979 Patients)
≥ 1 lesion with chronic total occlusion[c], no. (%)	24 (2.5)	22 (2.3)
≥ 1 lesion with in-stent restenosis[c], no. (%)	47 (4.9)	50 (5.1)
Mean reference vessel diameter per subject[c], mm	3.1 ± 0.5	3.1 ± 0.5
Mean diameter stenosis per subject[c], %	82.0 ± 11.8	82.2 ± 13.0
Mean lesion length per subject[c], mm	20.8 ± 11.1	21.3 ± 12.2
Multivessel intervention, no. (%)	210 (21.9)	181 (18.6)
Number of vessels treated per patient[d], no. (%)		
One	738 (77.0)	779 (80.1)
Two	173 (18.0)	150 (15.4)
Three	33 (3.4)	24 (2.5)
Number of stents per patient	1.7 ± 1.0	1.7 ± 1.0
Total stent length per patient	37.2 ± 25.4	36.7 ± 24.4
Any overlapping stenting, no. (%)	174 (18.0)	212 (21.7)

a Plus–minus values are means±SD.

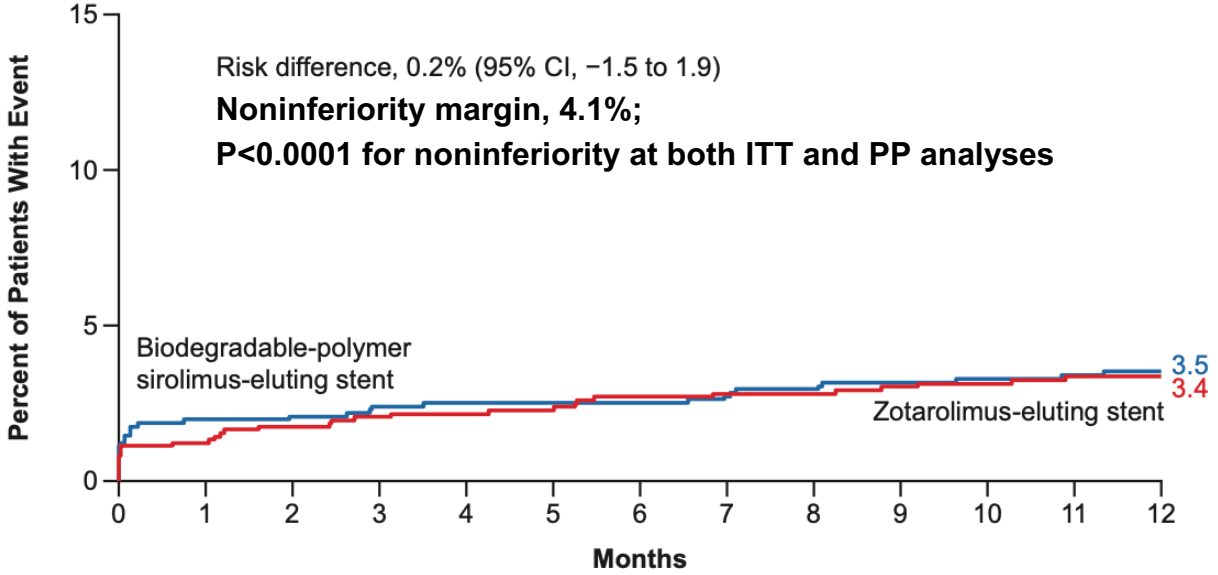
c Unknown for 10 patients in biodegradable-polymer stent group and 6 patients in the zotarolimus-eluting stent group (percentages were calculated using a total of 959 patients in the biodegradable-polymer stent group and 973 patients in the zotarolimus-eluting stent group).

d Four patients in the biodegradable-polymer stent group and 6 in the zotarolimus-eluting stent group had 4 treated vessels; 1 patient in the zotarolimus-eluting stent group had 5 treated vessels and 11 patient in biodegradable-polymer stent group and 13 in the zotarolimus-eluting stent group had only coronary artery bypass graft treatment.

Adherence to Antiplatelet Therapy after PCI



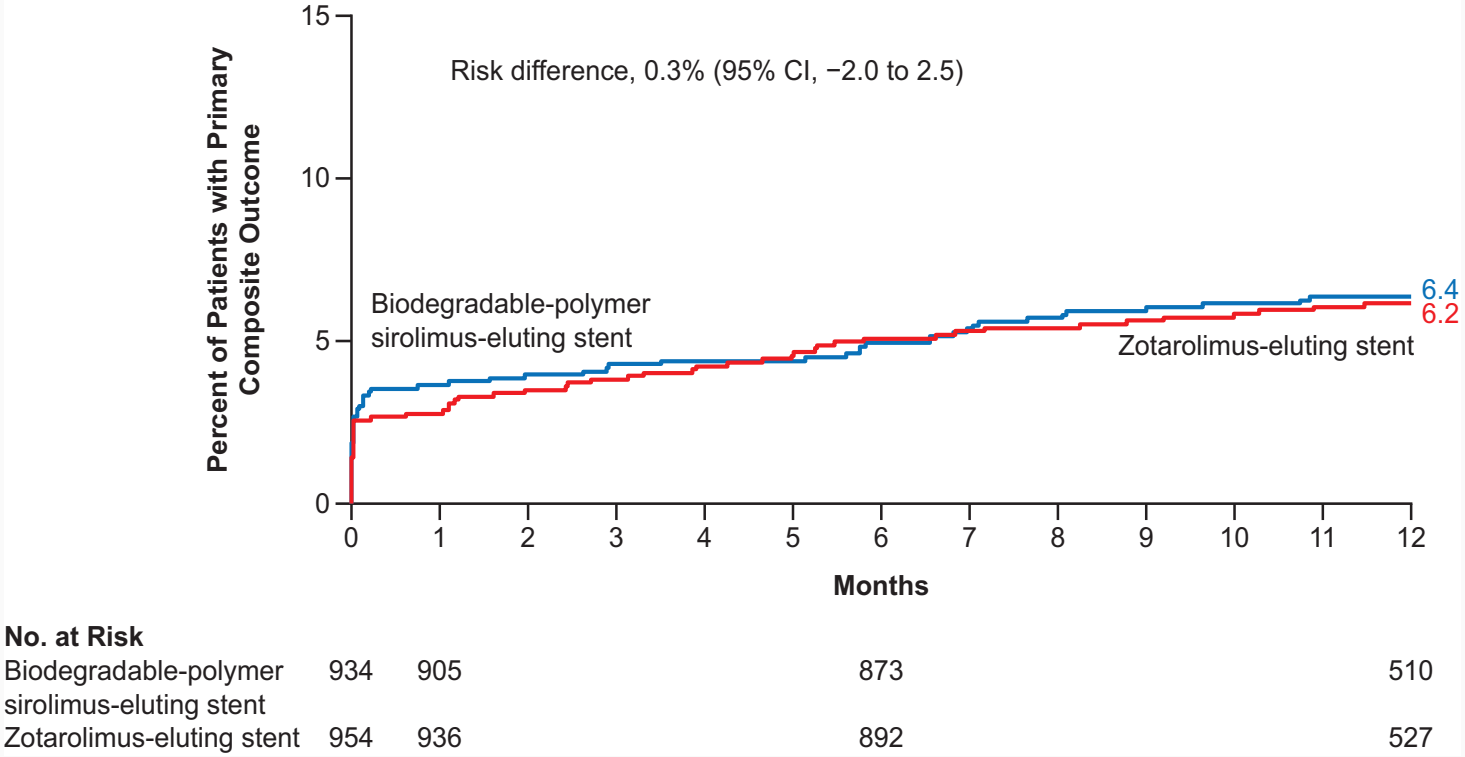
Primary Outcome: Cardiac Death, Myocardial Infarction*, or Stent Thrombosis



No. at Risk				
Biodegradable-polymer sirolimus-eluting stent	941	921	896	526
Zotarolimus-eluting stent	960	950	913	537

*ARC-2 definition

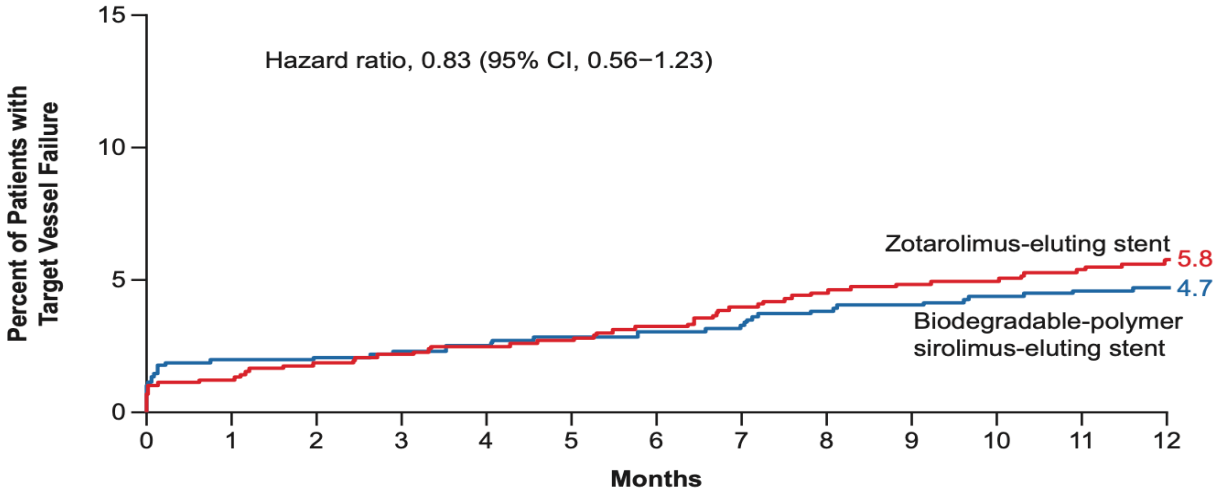
Prespecified EP: Cardiac Death, Myocardial Infarction*, or Stent Thrombosis



No. at Risk				
Biodegradable-polymer sirolimus-eluting stent	934	905	873	510
Zotarolimus-eluting stent	954	936	892	527

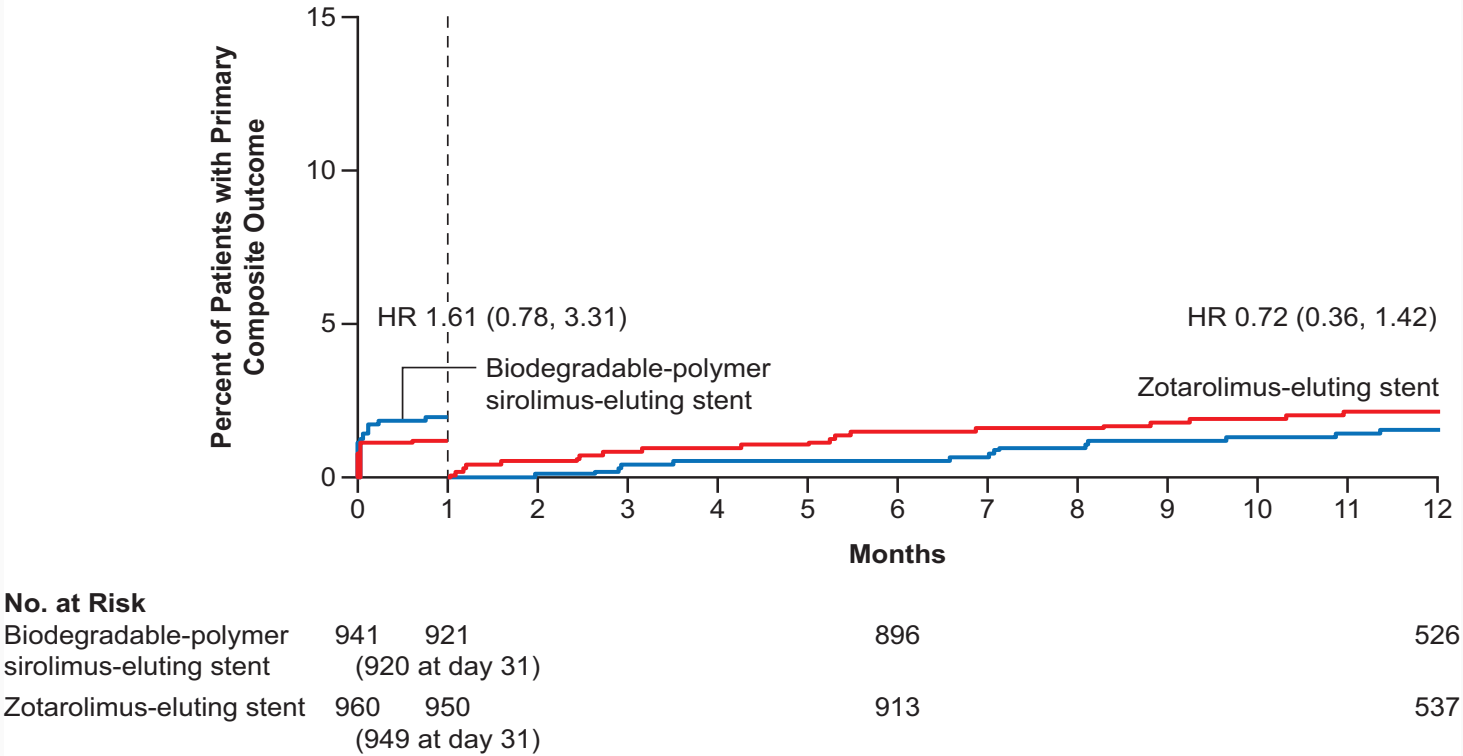
*Third Universal MI definition

Target Vessel Revascularization



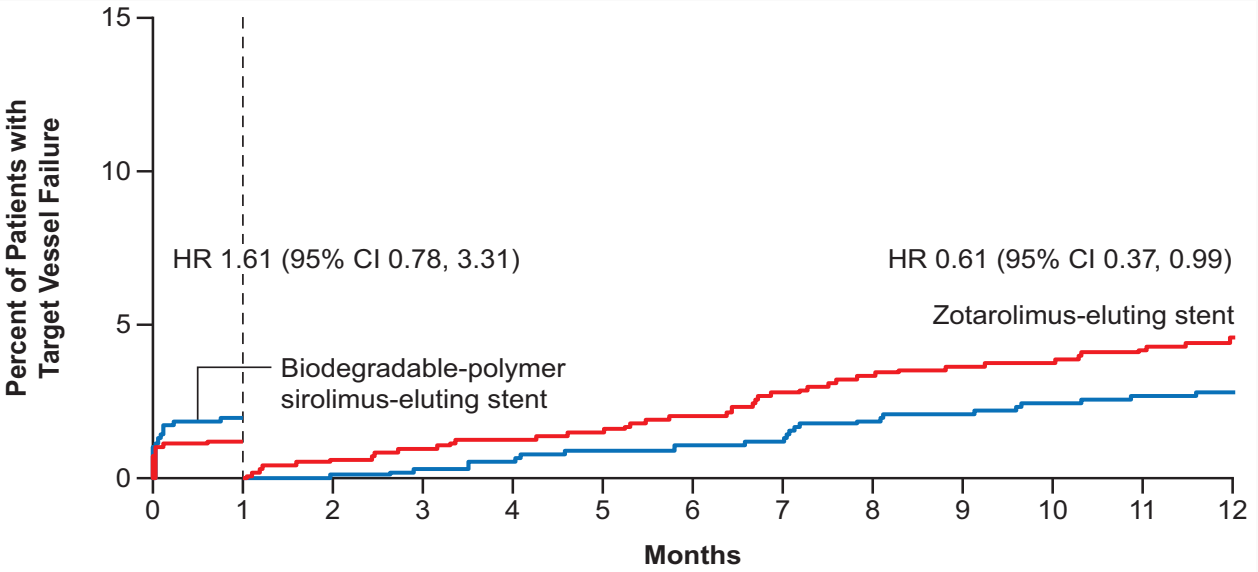
No. at Risk				
Biodegradable-polymer sirolimus-eluting stent	942	921	891	518
Zotarolimus-eluting stent	961	950	909	527

Prespecified Landmark Analysis at 30 days: Primary Endpoint*



*: ARC-2 definition

Prespecified Landmark Analysis at 30 days: Target Vessel Failure



No. at Risk

Biodegradable-polymer sirolimus-eluting stent	942	921 (920 at day 31)	891	518
Zotarolimus-eluting stent	961	950 (949 at day 31)	909	527

Limitations

- Incidences of outcome events at 1 year were lower than expected
- Treatments were open label
- Decision to continue aspirin or a $P2Y_{12}$ inhibitor was at the discretion of the physicians (Rx was stratified accordingly)
- Complete SDV was implemented in a random cohort of 28.2% of the patients
- Angiograms were not assessed by an independent core-laboratory

Conclusion

In patients at high risk for bleeding, a strategy of PCI with BP-SES (Orsiro) followed by 30 days of DAPT therapy was non-inferior to DP-ZES (Onyx) with respect to the incidence of death from cardiac causes, myocardial infarction, or stent thrombosis

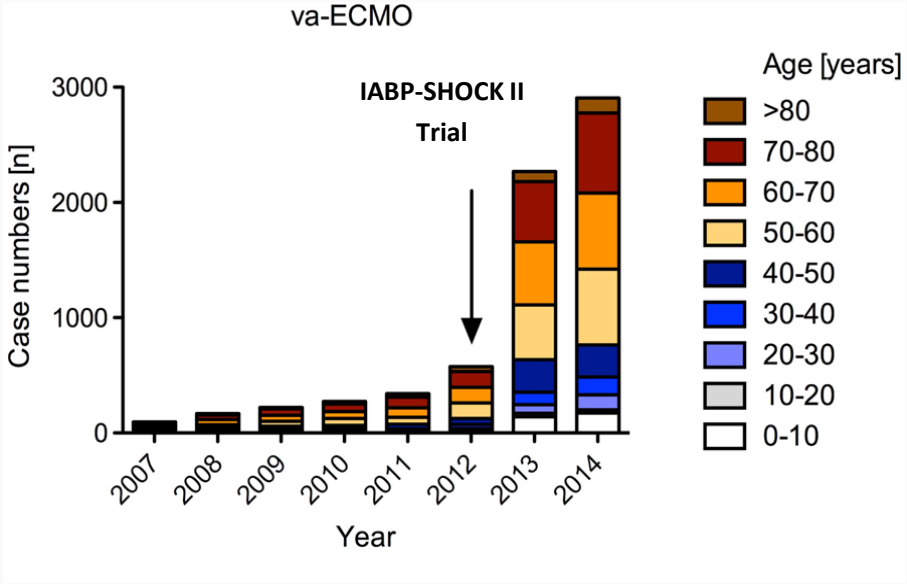
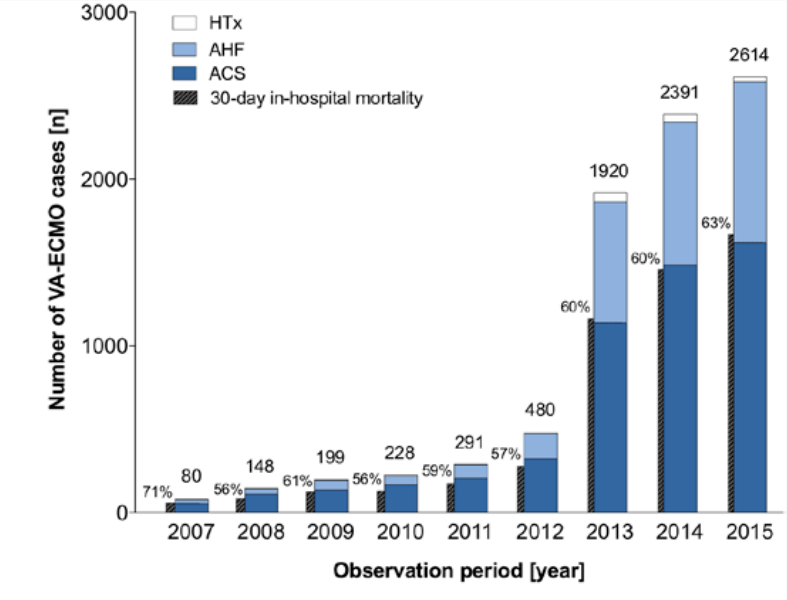
Increase in VA-ECMO (ECLS) Over Time





Karagiannidis et al. Intensive Care Med.2016;42:889–896
Becher et al. Circulation 2018;138:2298-2300

Endpoints/Statistical Methodology

ECLS-SHOCK

Primary endpoint

30-day all-cause mortality

Secondary endpoints

- Time to hemodynamic stabilization
- Duration of catecholamine therapy
- Serial creatinine-level and creatinine-clearance until hemodynamic stabilization
- Mean and area under the curve of arterial lactate during 48 hours after PCI
- Peak release of myocardial enzymes
- Serial SAPS II
- Length of mechanical ventilation
- Length of ICU stay
- Length of hospital stay
- Acute renal failure requiring renal replacement therapy within 30 days
- Recurrent myocardial infarction within 30 days
- Need for repeat revascularization (PCI and/or CABG) within 30-days
- Rehospitalization for heart failure within 30 days
- Cerebral performance category (CPC) at 30 days

Sample size

- **Estimated event rate** for primary endpoint**:**
  - **49%** in **control group** versus
  - **35%** in **ECLS group**
- 1 interim analysis (50% of patients)
- 2-sided Chi^2-test; power: 80%, alpha=0.048 for final analysis → **390 patients**
- To compensate for losses in follow-up → **420 patients**

Thiele et al. Am Heart J 2021;234: 1-1

In- and Exclusion Criteria

ECLS-SHOCK

Inclusion Criteria	Exclusion Criteria
• Cardiogenic shock complicating AMI (STEMI or NSTEMI) plus obligatory: 1. Planned revascularization 2. SBP <90 mmHg >30 min or catecholamines required to maintain SBP >90 mmHg 3. Signs of impaired organ perfusion with at least one of the following criteria: ➢ Altered mental status ➢ Cold, clammy skin and extremities ➢ Oliguria with urine output <30 ml/h 4. Arterial lactate >3 mmol/l • Informed consent	• Resuscitation >45 minutes • Mechanical cause of cardiogenic shock • Onset of shock >12 h • Severe peripheral artery disease with impossibility to insert ECLS cannulae • Age <18 years or >80 years • Shock of other cause (bradycardia, sepsis, hypovolemia, etc.) • Other severe concomitant disease with limited life expectancy <6 months • Pregnancy • Participation in another trial

Summary and Conclusions

ECLS-SHOCK

- In patients with acute myocardial infarction and cardiogenic shock with planned revascularization ECLS (VA-ECMO) versus control does not reduce 30-day all-cause mortality.
- This lack of mortality benefit is supported by an IPD metaanalysis of all 4 RCTs comparing ECLS vs control.
- This lack of mortality benefit is further supported by the fact that there were no differences in the secondary endpoints (e.g. lactate, renal function, duration of catecholamines, etc.).
- ECLS is associated with higher rates of moderate or severe BARC bleeding and peripheral ischemic complications requiring intervention.
- The findings challenge current guideline recommendations and clinical practice with increasing rates of mechanical circulatory support in cardiogenic shock.

Acknowledgments and Thank You

ADVENT trial

#ESCCongress

Pulsed field ablation vs. thermal ablation (RF/cryo) for paroxysmal AF

Conclusion

Pulsed field ablation (PFA) is noninferior to thermal ablation in paroxysmal atrial fibrillation (AF).

Impact on clinical practice

PFA is as effective and safe as conventional thermal ablation to treat paroxysmal AF.
Procedure times were faster for PFA than thermal ablation, but there was more X-ray exposure with PFA.

Study objectives

ADVENT was the first randomised controlled trial comparing PFA to conventional ablation (either radiofrequency or cryothermal ablation).

Study population

Patients with drug-resistant, symptomatic paroxysmal AF

Where?

United States — 30 centres

Who and what?

687 patients → 80 roll-in patients to gain experience with the PFA catheter

607 patients

Randomised 1:1

- **PFA**
- **Thermal ablation**: Radiofrequency or Cryothermal

12-month follow-up

Primary efficacy endpoint

Success rate, defined as acute success and chronic success (1-year freedom from recurrent atrial arrhythmias, antiarrhythmic drug use, and cardioversion or repeat ablation)

Rate%

- 73.3%
- 71.3%

Met the prespecified criteria for noninferiority: between-group difference, 2.0%; 95% Bayesian credible interval (BCI), -5.2 to 9.2%; posterior probability of noninferiority >0.999

Secondary efficacy endpoint

Same as the primary efficacy endpoint, but tested for superiority:
did not meet the criteria for superiority
(posterior probability of superiority 0.708)

Primary safety endpoint

Composite of serious adverse events related to use of an ablation catheter or the procedure itself and occurring within 7 days, as well as pulmonary vein stenosis or oesophageal fistula occurring at any time during the 12-month follow up

- 2.1%
- 1.5%

Met the prespecified criteria for noninferiority: between-group difference, 0.6%; 95% BCI, -1.5 to 2.8%; posterior probability of noninferiority >0.999

Secondary safety endpoint

Change in pulmonary vein dimension (i.e., any stenosis or narrowing) from baseline to day 90

Reductions in vein cross-sectional area

- 3.3%
- 19.5%

Met the prespecified criteria for superiority of PFA: posterior probability of superiority >0.999

ESC

OCT vs. IVUS vs. angiography guidance

A real-time updated network meta-analysis

#ESCCongress

Conclusion

Intravascular imaging (IVI)-guided percutaneous coronary intervention (PCI) is associated with a lower rate of target lesion failure compared with angiography-guided PCI.

Impact on clinical practice

These results emphasise the importance of physicians using IVI with either optical coherence tomography (OCT) or intravascular ultrasound (IVUS) to optimise stent outcomes and improve the long-term prognosis of their patients.

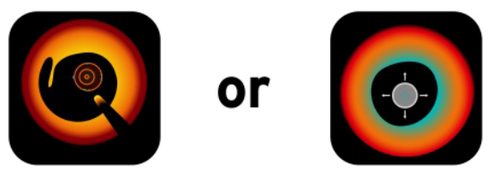
Study objectives

This real-time updated network meta-analysis, integrating data from the ILUMIEN IV and OCTOBER trials with prior studies, examined the effects of IVI-guided PCI versus angiography-guided PCI.

Who and what?

20 trials 12,428 patients randomised

IVI-guided PCI including:
OCT or IVUS



angiography-guided PCI

follow-up

between 6 months and 5 years

Primary endpoint

Target lesion failure, defined as a composite of cardiac death, target vessel myocardial infarction, or target lesion revascularisation.

Reduced by 31% with  vs. 

Secondary endpoints

Cardiac death reduced by 46% with  vs. 

Target vessel myocardial infarction reduced by 20% with  vs. 

Target lesion revascularisation reduced by 29% with  vs. 

Stent thrombosis reduced by 52% with  vs.

OPT-BIRISK trial

#ESCCongress

Extended clopidogrel monotherapy versus DAPT in high-risk patients

Conclusion

Extended P2Y12 inhibitor monotherapy beyond 12 months after percutaneous coronary intervention (PCI) reduces bleeding and ischaemic events in acute coronary syndrome (ACS) patients at high risk for both types of events.

Impact on clinical practice

Extended P2Y12 inhibitor monotherapy benefits high-risk ACS patients.

Study objectives

The OPT-BIRISK trial examined whether in ACS patients with both high bleeding and ischaemic risk characteristics who remained event-free after a standard course of dual antiplatelet therapy (DAPT) following PCI, an extended course of clopidogrel monotherapy would be superior to ongoing DAPT treatment with aspirin and clopidogrel.

Study population

Patients who

- completed 9 to 12 months of DAPT (aspirin plus either clopidogrel or ticagrelor) after drug-eluting stent implantation for the treatment of ACS
- were free from major adverse clinical events during the prior 6 months
- were at both high bleeding and ischaemic risk

Where?

ARREST trial

#ESCCongress

Expedited transfer to a cardiac arrest centre for OHCA

Conclusion

There was no difference in survival at 30 days in patients with resuscitated cardiac arrest in the community who were taken by ambulance to a cardiac arrest centre compared with those delivered to the geographically closest emergency department.

Impact on clinical practice

Ambulances should take cardiac arrest victims to the closest emergency department.

Study objectives

The ARREST trial investigated whether expedited transfer of out-of-hospital cardiac arrest (OHCA) patients to a cardiac arrest centre reduces mortality compared with delivery to the closest emergency department.

Study population

Colchicine for the prevention of perioperative atrial fibrillation after major thoracic surgery

Conclusion

Colchicine does not significantly reduce perioperative atrial fibrillation (AF) or myocardial injury after non-cardiac surgery (MINS) in patients undergoing major non-cardiac thoracic surgery.

Impact on clinical practice

Despite no significant reduction in the co-primary outcomes with colchicine and an increased risk of non-infectious diarrhoea, several results provided an encouraging signal of benefit for colchicine to reduce the incidence of adverse CV outcomes in these patients.

Study objectives

The COP-AF trial tested the hypothesis that colchicine reduces the incidence of clinically important perioperative AF and MINS in patients undergoing major non-cardiac thoracic surgery.

Study population

Patients

- aged ≥55 years
- were undergoing major non-cardiac thoracic surgery.

Effects of FCM on recurrent HF hospitalisations

An individual participant data meta-analysis

#ESCCongress

Conclusion

In iron-deficient patients with heart failure (HF) and reduced or mildly reduced left ventricular ejection fraction (LVEF), intravenous ferric carboxymaltose (FCM) is associated with a reduced risk of the composite outcome of total CV hospitalisation and CV death through 52 weeks compared with placebo.

Impact on clinical practice

Intravenous FCM should be considered in iron-deficient patients with HF and reduced or mildly reduced LVEF to reduce the risk of hospitalisation due to HF and CV causes.

Study objectives

The meta-analysis evaluated the effects of FCM therapy on hospitalisations and mortality in iron-deficient patients with HF and reduced or mildly reduced LVEF.

Study population

Individual participant data were pooled from 3 randomised, placebo-controlled trials of FCM in adult patients with HF and iron deficiency with ≥52 weeks of follow up: CONFIRM-HF, AFFIRM-AHF and HEART-FID.

Who and what?

ABSTRACT

A 58-year-old female patient was admitted to the Cardiology Department of our hospital for intermittent chest pain for 5 years and aggravation for a week. She had been diagnosed with polycythemia vera 8 years ago.Coronary angiography showed haze lesions in mid right coronary artery, mid left circumflex, and proximal left anterior descending artery. Optical coherence tomography in LAD showed diffused multiple channels within the lumen which are consistent with woven coronary artery. Thromboembolism is the most common complication of polycythemia vera. Therefore, we speculate that the woven coronary artery is caused by thrombotic recanalization.

Keywords

Woven coronary artery; thrombotic recanalization; polycythemia vera; Optical coherence tomography

1.Introduction

Woven coronary artery is a rare anomaly characterized by multiple interlacing micro channel bifurcations and woven found incidentally in coronary angiography. Some scholars think that this is a congenital coronary anomaly and benign condition[1].However,others think it might be mimicked by thrombotic recanalization[2]. Thromboembolism is the most common complication of polycythemia vera. Here, we reported a case of woven coronary arteries in a patient with polycythemia vera.

2. Case introduction

A 58-year-old female patient was admitted to the Cardiology Department of our hospital due to intermittent chest pain for 5 years and aggravation for a week. The patient had a history of hypertension for 10 years, with a highest blood pressure of 150/100 mmHg, which was controlled by oral amlodipine 1 tablet once daily and history of cerebral infarction for 23 years. She has been diagnosed with polycythemia vera for 8 years and took hydroxyurea 0.5g once daily. Physical examination: the body temperature was 36.5℃, pulse 76 beats/min, blood pressure 138/70mmHg(1 mmHg=0.133 kPa), and she was not in acute distress. Routine blood test revealed white blood cell count $3.65*10^9$/L (reference interval 3.50-9.50*10^9/L), red blood cell count $8.15*10^{12}$/L (reference interval 3.80-5.10*10^9/L), and hemoglobin count 237g/L (reference interval 115-150g/L). Platelet count $265*10^9$/L (reference interval 125-350*10^9/L); Routine coagulation, liver function, renal function, biochemical, and myocardial injury markers were normal. Bone marrow cytology showed proliferation of granulocyte, red and megakaryocyte lineages, and JAK2-V617 mutation was detected by gene screening. Electrocardiogram showed

sinus rhythm and poor R-wave progression in leads V1-V3 (Figure 1). Echocardiography showed left ventricular ejection fraction 46%, left atrial diameter 44mm, left ventricular end-diastolic diameter 62mm, interventricular septal thickness 12mm, and left ventricular wall segmental motion abnormality. Coronary angiography showed haze lesion in the middle to proximal segment of the left anterior descending artery (LAD) with forward flow TIMI grade 3(Figure 2A). Suspected thrombus in the left circumflex artery (LCX) was observed in the middle to proximal segment and the forward flow of TIMI was grade 3(Figure 2B). The right coronary artery (RCA) showed aneurysmal dilatation in the proximal segment and suspected thrombus in the middle segment with forward flow TIMI grade 3 (Figure 2C). Optical coherence tomography(OCT) performed in LAD showed organized thrombi separate the lumen into multiple micro channels. Clinical diagnosis: Coronary artery heart disease, stable angina, polycythemia vera, Hypertension. Considering the high risk of thrombosis with the condition of the polycythemia vera, and the high possibility of the side branch loss with stenting, the patient was discharged home without coronary intervention. The discharge medicine includingaspirin 100mg once daily, atorvastatin 20mg once daily, metoprolol 47.5mg once daily, amlodipine 1 tablet once daily, hydroxyurea 0.5g once daily. The patient was in stable condition in 3 months follow-up.

3.Discussion

Here we are reporting 1st case of woven coronary arteries in a patient with polythythemia vera. Woven coronary artery is a rare anomaly characterized by multiple interlacing micro channel bifurcations and woven found incidentally in coronary angiography. Some scholars think that this is a congenital anomaly [1], while others believe that it is caused by recanalization of coronary thrombosis [2].At first, it was considered to be a benign condition [3], but later studies found that this variant could cause thrombosis and sudden cardiac death [4, 5].The complex intra-coronary channels affect the flow and causing pressure drop in the distal blood perfusion, particulary for those with more complex micro channel and extended lesion length [5].Although the woven coronary artery showed normal TIMI flow or visual stenosis < 70% on angiography, their sensitivity and specificity in the assessment of ischemia is limited. Intravascular imaging such as OCT can be very helpful in clarifying the intracoronary artery structions and detection of intracoronary thrombus [1].Fractional flow reserve may be the most appropriate method to assess the severity of ischemia [5].Polycythemia vera is the most common disease in myeloproliferative neoplasms and thromboembolism is the most common complication and cause of death[6]. The incidence of thromboembolism is 46%, and the incidence of arterial thrombosis is 2 to 3 times that of venous thrombosis[7]. This patient was hospitalized for cerebral infarction more than 20 years ago, and blood routine examination showed that the red blood cell count was increased abnormally. Polycythemia vera diagnosis was established with bone marrow biopsy 8 years ago. It was speculated and the blood viscosity caused by polycythemia led to cerebral infarction. The coronary artery change confirmed by the OCT are consistent with the organized thrombus based on the angiographic manifestation. We assume the lesion in the LCX and RCA are likely another organized thrombus, which are all complications of polycythemia vera.

Currently, there are no guidelines for the treatment of woven coronary artery. Surgical bypass surgery [1], and coronary artery intervention with stenting has been proposed as treatment options[8]. However, due to the distortion of the channel, the woven coronary artery may lead to the difficulty of wiring and device delivery. Endothelialization of the tissue separating the

multiple channel may cause the occlusion of the side branch. Therefore the treatment strategy should be prudent and individualized for patient with extremely high risk of thromobosis, conservative therapy without stenting probably is safier as with this patient. 3 month follow-up showed that the patient's chest pain was relieved, without any cardiac event.

Clinical Findings	**6**	She has been diagnosed with polycythemia vera for 8 years and took hydroxyurea 0.5g once daily.Routine blood test revealed red blood cell count 8.15*1012/L (reference interval 3.80-5.10*109/L), and hemoglobin count 237g/L (reference interval 115-150g/L). Bone marrow cytology showed proliferation of granulocyte, red and megakaryocyte lineages, and JAK2-V617 mutation was detected by gene screening.	
Timeline	**7**	The history of cerebral infarction for 23 years,diagnosed with polycythemia vera for 8 years, intermittent chest pain for 5 years and aggravation for a week.	
Diagnostic Assessment	8a	Routine blood test revealed white blood cell count 3.65*109/L (reference interval 3.50-9.50*109/L), red blood cell count 8.15*1012/L (reference interval 3.80-5.10*109/L), and hemoglobin count 237g/L (reference interval 115-150g/L). Platelet count 265*109/L (reference interval 125-350*109/L).Bone marrow cytology showed proliferation of granulocyte, red and megakaryocyte lineages, and JAK2-V617 mutation was detected by gene screening.Electrocardiogram showed sinus rhythm and poor R-wave progression in leads V1-V3 (Figure 1).	

Echocardiography showed left ventricular ejection fraction 46%, left atrial diameter 44mm, left ventricular end-diastolic diameter 62mm, interventricular septal thickness 12mm, and left ventricular wall segmental motion abnormality. Coronary angiography showed haze lesion in the middle to proximal segment of the left anterior descending artery (LAD) with forward flow TIMI grade 3(Figure 2A). Suspected thrombus in the left circumflex artery (LCX) was observed in the middle to proximal segment and the forward flow of TIMI was grade 3(Figure 2B). The right coronary artery (RCA) showed aneurysmal dilatation in the proximal segment and suspected thrombus in the middle segment with forward flow TIMI grade 3 (Figure 2C). Optical coherence tomography(OCT) performed in LAD showed organized thrombi separate the lumen into multiple micro channels.

8b No diagnostic challenges.

8c Clinical diagnosis: Coronary artery heart disease, stable angina, polycythemia vera, Hypertension.

8d No Prognosis

Therapeutic Intervention

9a Type of therapeutic intervention: pharmacologic

9b Aspirin 100mg once daily, atorvastatin 20mg once daily, metoprolol 47.5mg once daily, amlodipine 1 tablet once daily, hydroxyurea 0.5g once daily.

9c No changes in therapeutic intervention

Follow-up and Outcomes

10a The patient was in stable condition in 3 months follow-up.

10b No important follow-up diagnostic and other test results.

10c The patient followed the doctor's advice and adhered to the medication in 3 months follow-up.

10d No adverse and unanticipated events.

Discussion

11a This is the first report of woven coronary arteries in a patient with polythythemia vera.This patient was hospitalized for cerebral infarction more than 20 years ago, and blood routine examination showed that the red blood cell count was increased abnormally.Polycythemia vera diagnosis was established with bone marrow biopsy 8 years ago. It was speculated and the blood viscosity caused by polycythemia led to cerebral infarction. The coronary artery change confirmed by the OCT are consistent with the organized thrombus based on the angiographic manifestation. We assume the lesion in the LCX and RCA are likely another organized thrombus, which are all complications of polycythemia vera.

11b Some scholars think that this is a congenital anomaly [1], while others believe that it is caused by recanalization of coronary thrombosis [2].At first, it was considered to be a benign condition [3], but later studies found that this variant could cause thrombosis and sudden cardiac death [4, 5].The complex intra-coronary channels affect the flow and causing pressure drop in the distal blood perfusion, particulary for those with more complex micro channel and extended lesion length [5].Although the woven coronary artery showed normal TIMI flow or visual stenosis < 70% on angiography, their sensitivity and specificity in the assessment of ischemia is limited. Intravascular imaging such as OCT can be very helpful in clarifying the intracoronary artery structions and detection of intracoronary thrombus [1].Fractional flow reserve may be the most appropriate method to assess the severity of ischemia [5].Polycythemia vera is the most common disease in myeloproliferative neoplasms and thromboembolism is the most common complication and cause of death.Currently, there are no guidelines for the treatment of woven coronary artery. Surgical bypass surgery [1], and coronary artery intervention with stenting has been proposed as treatment options[8].

11c The treatment strategy should be prudent and individualized for patient with extremely high risk of thromobosis, conservative therapy without stenting probably is safier as with this patient.

11d Due to the distortion of the channel, the woven coronary artery may lead to the difficulty of wiring and device delivery. Endothelialization of the tissue separating the multiple channel may cause the occlusion of the side branch. The treatment strategy should be prudent and individualized for patient with extremely high risk of thromobosis, conservative therapy without stenting probably is safier as with this patient.

Patient Perspective

12a The patient's chest tightness was relieved, and the condition was in a stable stage. She took drugs on time and came to the hospital for regular follow-up.

Intravascular Imaging Guidance for PCI:

A "Real-Time" Updated Network Meta-analysis

Gregg W. Stone MD

on behalf of

Evald H. Christiansen, Ziad A. Ali, Lene N Andreasen,
Akiko Maehara, Yousif Ahmad, Ulf Landmesser, Niels R. Holm

Background

- Prior meta-analyses of intravascular imaging (IVI) guidance vs. angiography guidance of PCI procedures have generally shown reductions in MACE with IVI guidance, although none have shown a reduction in all-cause death or all MI, and few prior studies included OCT guidance

- At the 2023 ESC annual scientific sessions, two new major RCTs of OCT-guided vs. angiography-guided PCI have been presented, the international ILUMIEN IV trial in high-risk pts and complex lesions (n=2487) and the EU-based OCTOBER trial in bifurcation lesions (n=1201)

- The ILUMIEN IV and OCTOBER investigators have collaborated to prepare an updated “real-time” network meta-analysis to examine the effects of IVI guidance vs. angiography guidance and OCT vs. IVUS vs. angiography guidance in patients undergoing PCI

Methods 1

- **PRISMA guidance** was followed for systematic reviews and network meta-analyses and this study has been registered with **PROSPERO**
- **A systematic search** was performed for all RCTs of OCT-guided and IVUS-guided PCI
- **The longest available follow-up duration** was used for each trial; outcomes are expressed as relative risks (RR) with 95% confidence intervals (CI)
- **Direct evidence** was generated from 2-stage meta-analysis (prioritizing random effects > fixed effects)
- **Network meta-analysis** was performed to generate **indirect data** and **overall treatment effects** - specified as the **primary analysis** for this study

Methods 2

- **Pre-specified primary analysis:** IVI-guided PCI (OCT-guided or IVUS-guided or both) vs. angiography-guided PCI
- **Pre-specified secondary analyses:** IVUS-guided vs. angiography-guided PCI, OCT-guided vs. angiography-guided PCI, and OCT-guided vs. IVUS-guided PCI
- **Primary outcome measure was TLF** (cardiac death, TV-MI or ID/CD TLR)
- **Secondary outcomes:** TLF components, all-cause death, all MI, ID/CD TVR, definite or probable stent thrombosis
- **Rules for component outcomes:**
  - If cardiac (or CV) death unavailable, use all-cause death
  - If TV-MI unavailable, use all MI
  - If TLR unavailable, use TVR
  - If definite or probable ST unavailable, use definite ST

Summary of Included Studies

20 randomized trials

(publication years 2010 – 2023)

12,428 randomized patients

(range 85 – 2487 pts per trial)

IVUS: 13 randomized arms, 3120 pts

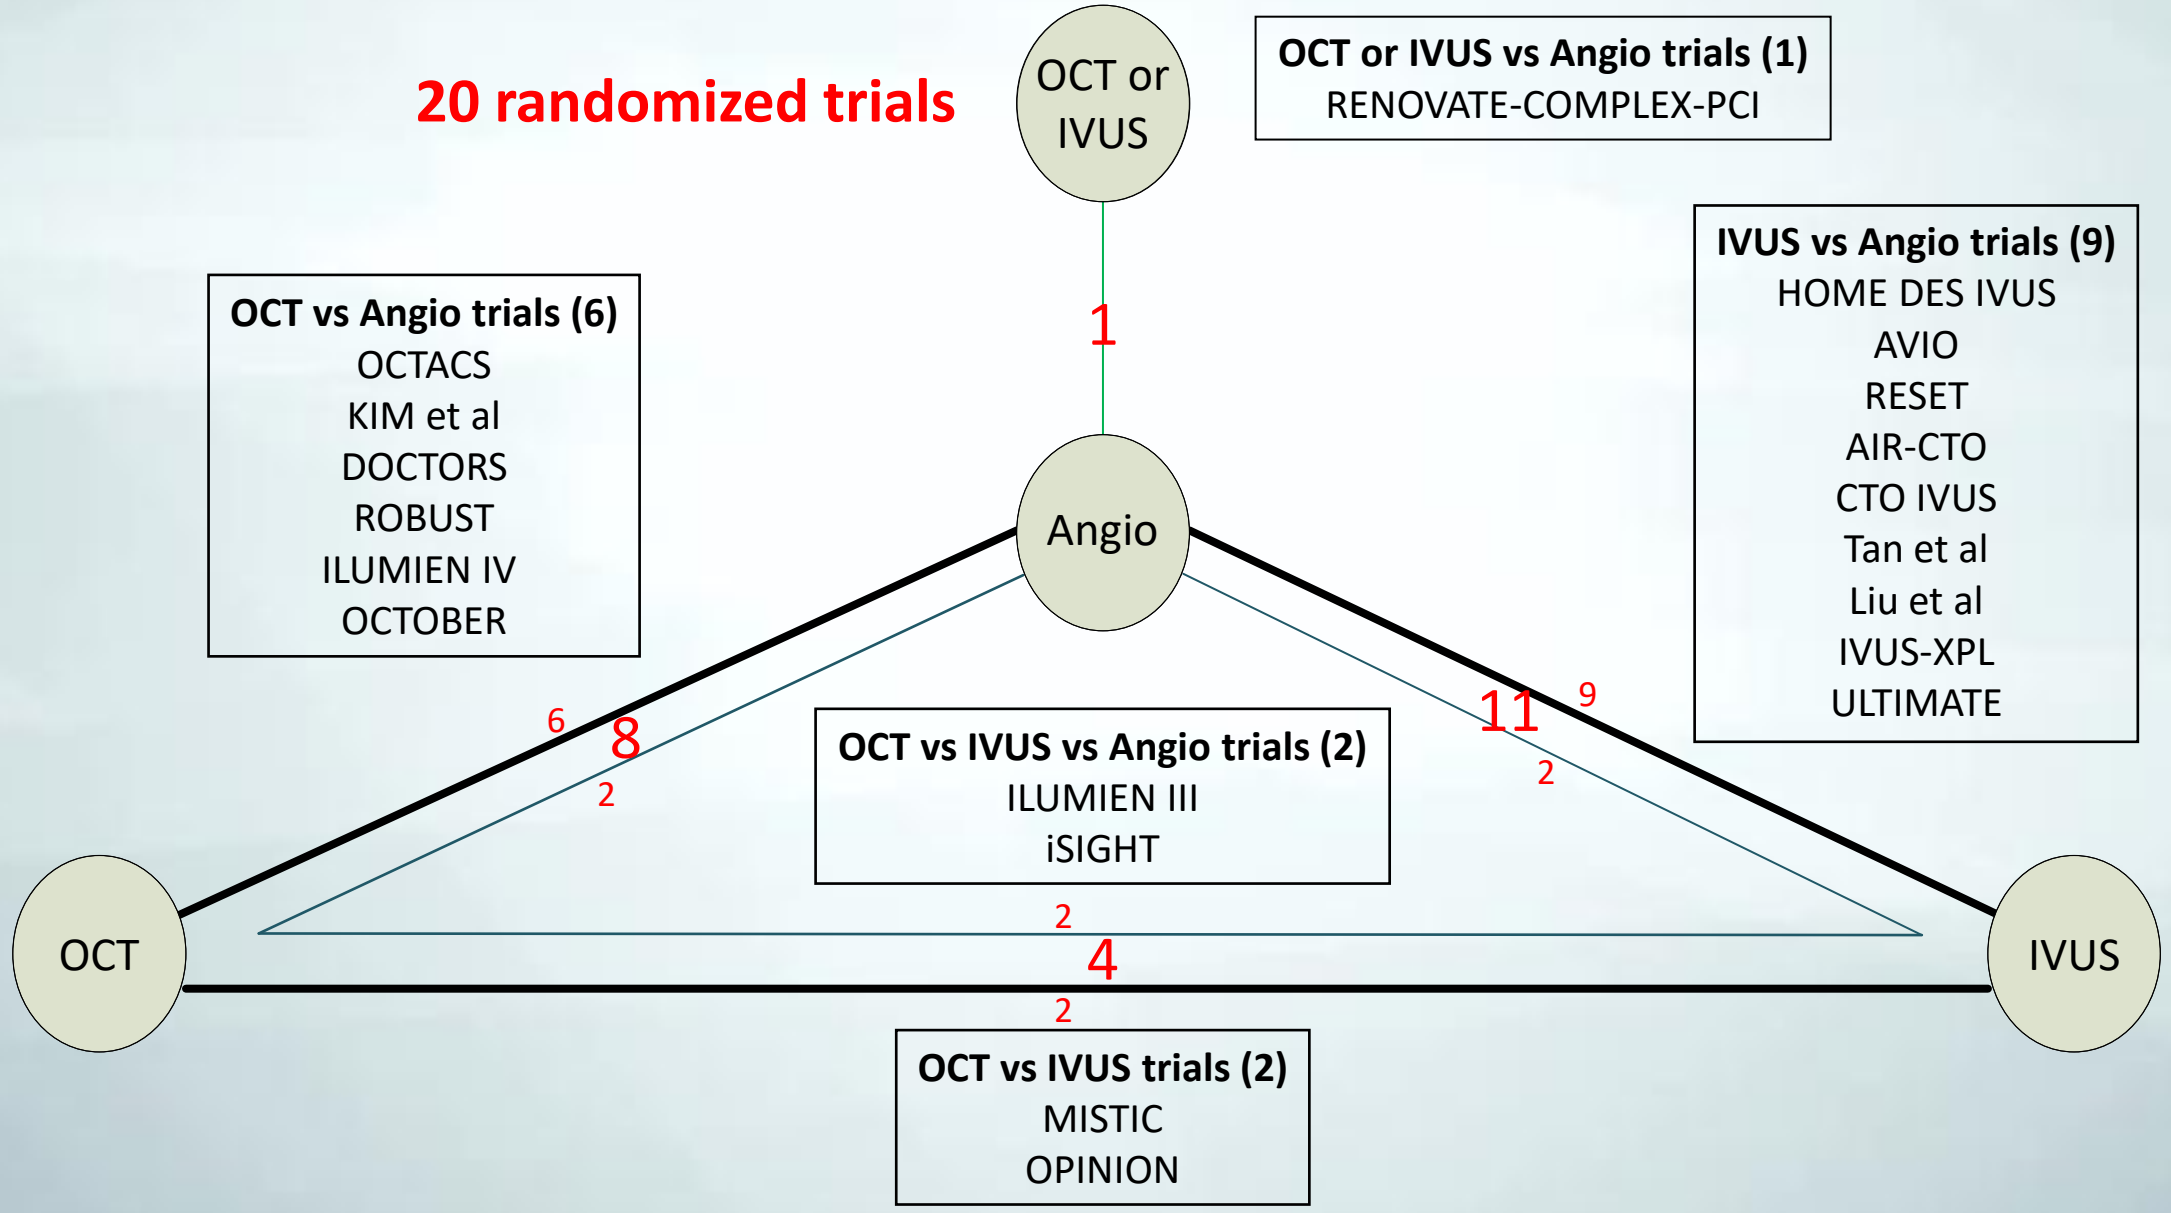
OCT: 10 randomized arms, 2826 pts

OCT or IVUS: 1 randomized arm, 1092 pts

Angiography: 18 randomized arms, 5390 pts

Longest FU: Range 6 – 60 months (weighted mean 26.4 mo)

Nodal Map of Direct Relationships



TLF (Direct Evidence): IV Imaging (OCT or IVUS) vs. Angio

18 trials, 11,502 patients, 963 events

TLF (Network Evidence): Bayesian vs. Frequentist Estimates

	Frequentist RR (95% CI)	Bayesian RR (95% CrI)
IVI (OCT or IVUS) vs. Angio		
Direct estimate (18 trials)	0.68 (0.56, 0.84)	0.69 (0.61, 0.79)
Indirect estimate	-	-
Network estimate	0.68 (0.56, 0.84)	0.69 (0.61, 0.79)
IVUS vs. Angio		
Direct estimate (11 trials)	0.63 (0.53, 0.75)	0.62 (0.53, 0.75)
Indirect estimate	0.92 (0.48, 1.76)	1.00 (0.46, 1.95)
Network estimate	0.65 (0.55, 0.77)	0.65 (0.55, 0.77)
OCT vs. Angio		
Direct estimate (8 trials)	0.83 (0.68, 1.02)	0.85 (0.68, 1.06)
Indirect estimate	0.50 (0.27, 0.96)	0.54 (0.27, 1.13)
Network estimate	0.79 (0.65, 0.97)	0.79 (0.65, 0.99)
OCT vs. IVUS		
Direct estimate (4 trials)	0.89 (0.51, 1.57)	0.92 (0.52, 1.69)
Indirect estimate	1.32 (1.00, 1.73)	1.33 (0.98, 1.80)
Network estimate	1.22 (0.96, 1.56)	1.23 (0.93, 1.60)

Limitations

- The limitations of all meta-analyses apply, acknowledging inter-study differences in study design, patient characteristics, geography, operators, technique, collected data, endpoint definitions, and follow-up duration
- The evidence is very robust for all IVI-guided PCI vs angiography-guided PCI, especially for the composite TLF outcome
- Given the fewer numbers of trials and events, the data are less determinative for some of the the pairwise comparisons and non-composite outcomes
  - In particular, prior to this congress, OCT vs. IVUS guidance of PCI had been directly compared in only 4 RCTs (1316 pts)
  - Most of the network evidence for this comparison was therefore “indirect”
  - As the largest completed OCT-guided vs IVUS-guided PCI trial, the just presented OCTIVUS trial will have a major effect on these estimates

Conclusions

The present network meta-analysis from 20 RCTs in 12,428 pts with follow-up ranging from 6-60 months demonstrates that:

- Compared with angiography-guided PCI, IVI-guided PCI with OCT or IVUS reduces **TLF by 31%,** driven by 46%, 20%, and 29% reductions in cardiac death, TV-MI, and ID/CD TLR respectively
- IVI-guided PCI also reduces **stent thrombosis by 52%,** all MI by 18%, and **all-cause death by 25%**
- Outcomes were similar for OCT-guided PCI and IVUS-guided PCI

Implications for Patient Care and Future Research

- **The routine use of OCT or IVUS to guide most PCI procedures will substantially improve patient event-free survival, enhancing both the long-term safety and effectiveness of the procedure**
- Additional investigation is required to determine:
  - Which lesion types most benefit from IVI guidance
  - The optimal technique and procedural objectives for OCT-guided and IVUS-guided stent implantation
  - Whether there are subtle differences in outcomes between OCT and IVUS guidance of PCI procedures

Edoxaban for 3 months versus 12 months in cancer patients with isolated distal deep vein thrombosis: ONCO DVT Study

Yugo Yamashita

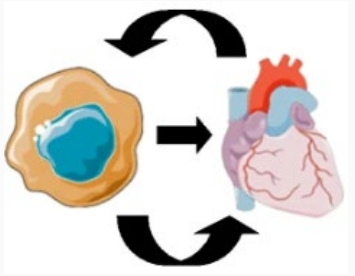
Department of Cardiovascular Medicine, Graduate School of Medicine, Kyoto University

HOT LINE 9; 28 August 2023; 16:50-

Declaration of interest

- Research contracts : Funding was provided by Daiichi Sankyo Company, Limited, which had no role in the study design, data collection, analysis, interpretation, or writing of the report.
- Others : Dr. Yamashita received lecture fees from Bayer Healthcare, Bristol-Myers Squibb, Pfizer, and Daiichi Sankyo, and grant support from Bayer Healthcare and Daiichi Sankyo.

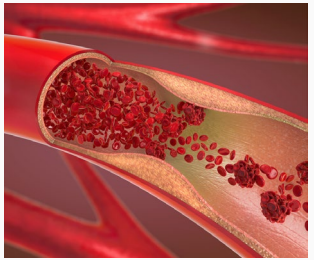
Background



- **Cancer** patients: Surviving longer

---> **Cardiovascular complications ↑↑**: **cardio-oncology**.

(Eur Heart J. 2022;43:4229-4361.)



- **Venous thromboembolism** (VTE): Risk of **recurrence**.

---> Can be **prevented** by **anticoagulation therapy**.

(Lancet. 2010;376:2032-9.)

- Isolated **distal** deep vein thrombosis (**DVT**): Common

---> More benign or not than a **proximal** DVT?

(Thromb Res. 2014;134:36-40. J Vasc Surg. 2012;55:550-61.)

Background

- **Guidelines recommendations** for isolated distal DVT (ACCP/CHEST)

---> **Anticoagulation of prolonged** duration for **cancer** patients

(**Weak** recommendation, **Low-certainty** evidence)

(Chest. 2021;160:e545-e608.)

- **Previous RCTs** for distal DVT (CACTUS [2016], RIDTS [2022])

---> **Excluded** patients with **active cancer**

(Lancet Haematol. 2016;3:e556-e562. BMJ. 2022;379:e072623.)

- **No RCT** for optimal duration of anticoagulation therapy for **cancer patients**

Purpose of the ONCO DVT study

To compare 12-month edoxaban treatment with 3-month edoxaban treatment in cancer patients with isolated distal DVT in a randomized clinical trial.

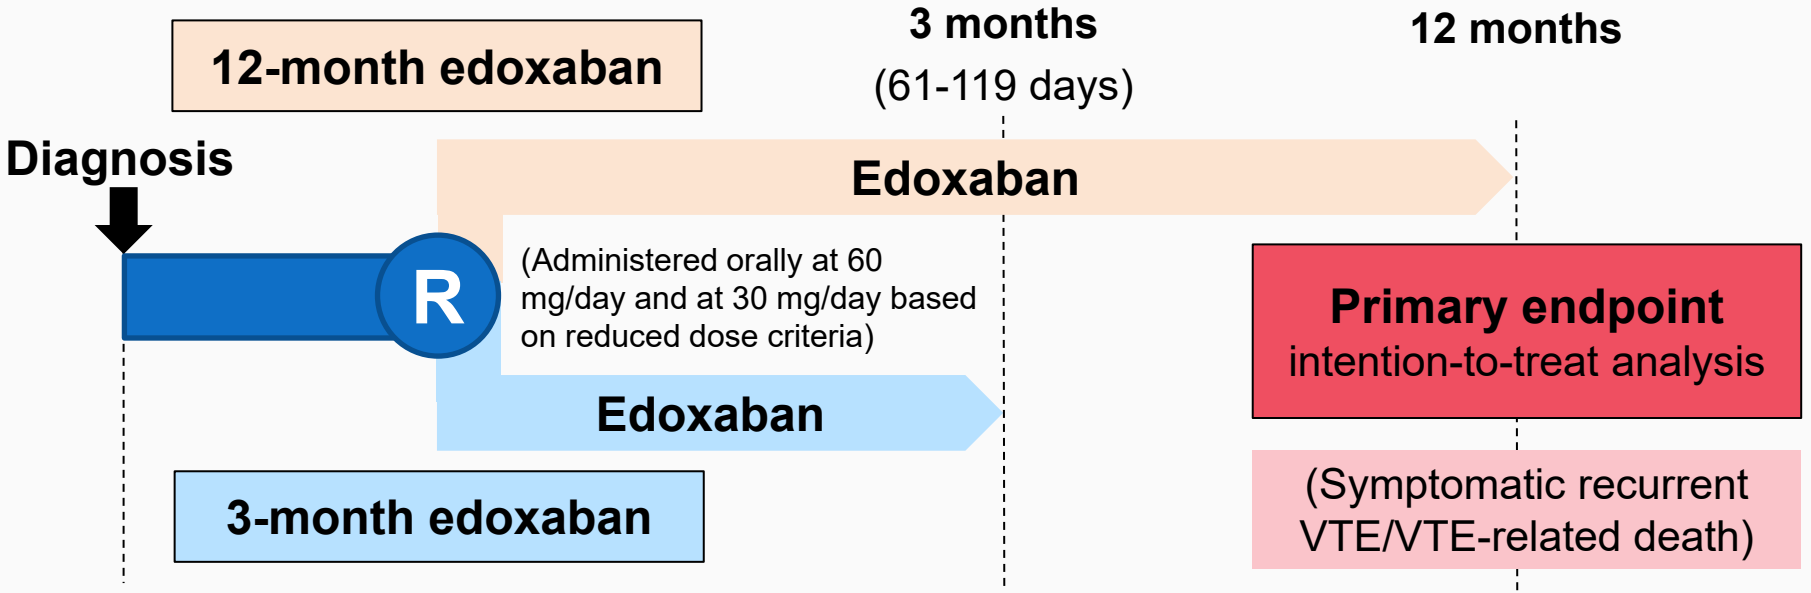
ONCO DVT Study: NCT03895502

(Optimal duration of anticoagulation therapy for isolated distal deep vein thrombosis in patients with cancer study)

Study design: ONCO DVT study

(A multicenter, open-label, adjudicator-blinded, randomized clinical trial)

Patients with active cancer who were newly diagnosed with isolated distal DVT confirmed by ultrasonography were eligible for inclusion.



Inclusion and Exclusion Criteria

Key Inclusion Criteria

- ✓ A new diagnosis of DVT objectively confirmed by ultrasonography
- ✓ With active cancer at randomization
- ✓ Scheduled for DVT treatment with anticoagulation therapy

Key Exclusion Criteria

- ✓ Already on anticoagulation therapy at the time of the diagnosis
- ✓ With pulmonary embolism
- ✓ Expected to have a life prognosis of 3 months or less

Endpoints

- **Primary endpoint (ITT analysis)**
  - ✓ Symptomatic recurrent VTE or VTE-related death at 12 months
- **Major secondary endpoint (ITT analysis)**
  - ✓ A major bleeding event (ISTH criteria definition) at 12 months

Sample Size Calculation

- **Hypothesis: Superiority of 12-month to 3-month edoxaban for the primary endpoint at 12 months**
- Assumption: Event rate at 12-month: 6% (12-month group)
  13% (3-month group)
- Randomization ratio: 1:1
- Power: 80%
- Two-sided alpha: 0.05
- Sample size: 550 patients (275 in each arm)
- Considering the potential dropouts: **600** patients

4
12-month edoxban better
3-month edoxban better

Study limitations

- Open-label design (although blinded endpoint adjudication)
- Lower event rates of the primary endpoints than expected
- Not-high adherence to the study protocol as to edoxaban treatment
- Differences of races and a variety of cancer types (generalizability)

Conclusions

In cancer patients with isolated distal DVT, edoxaban treatment for 12 months was superior to 3 months with respect to the composite outcome of a symptomatic recurrent VTE or VTE-related death.

The QUALIREHAB trial

Early hybrid cardiac rehabilitation in adolescents and young adults with congenital heart disease: a multicentre randomised controlled trial

Pascal AMEDRO

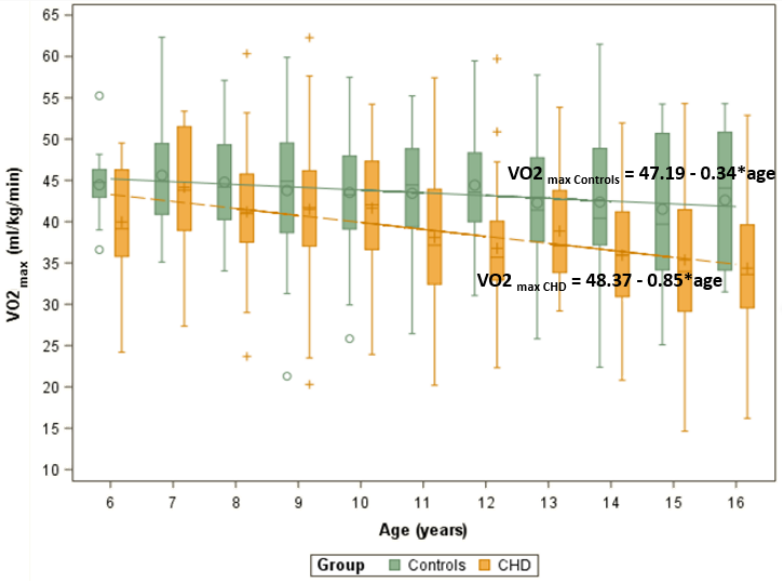
August 25th 2023

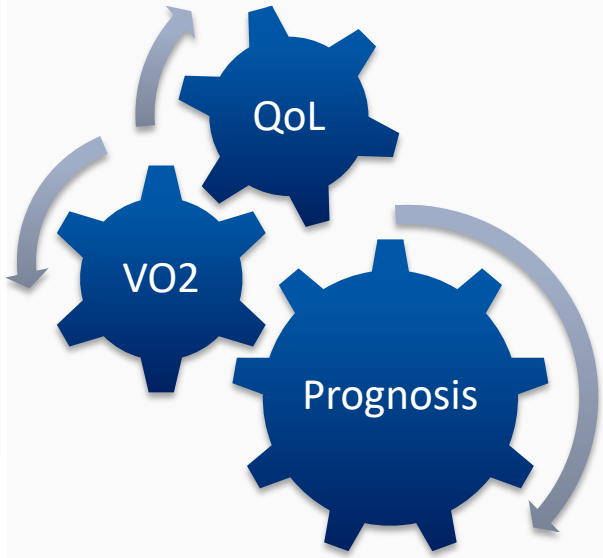
Early onset of physical deconditioning in youth with CHD

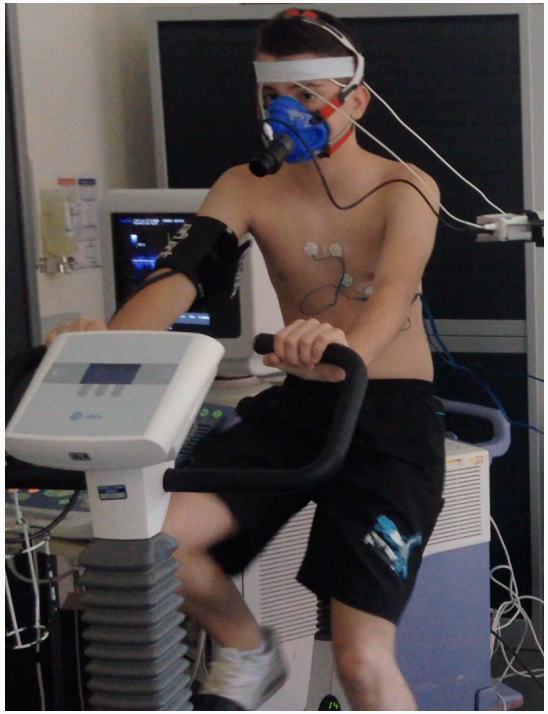
VO_{2max} decrease = -2 % per year vs. -0.4% per year (*P<0.01*)

Low ventilatory anaerobic threshold (VAT): 18% vs 6% (*P<0.01*)

VO_{2max} & VAT correlate with HRQoL in children with CHD

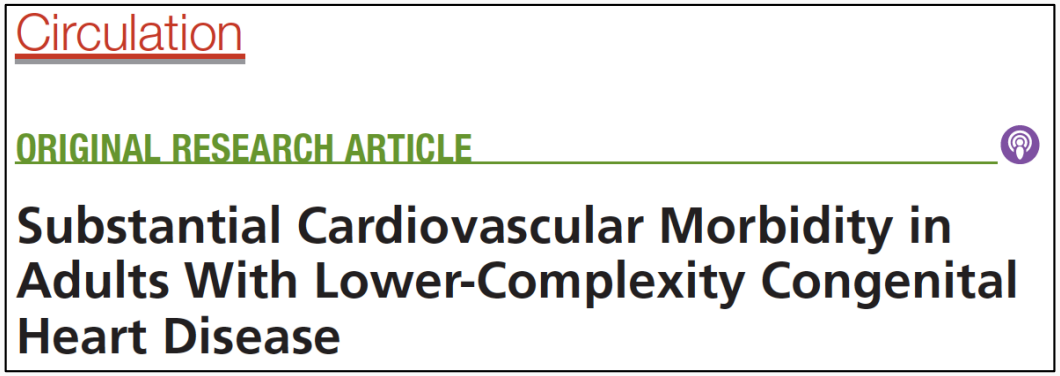






Amedro et al. *Heart* 2018
Amedro et al. *Int J Cardiol* 2019
Gavotto et al. *Int J Cardiol* 2023

Consequences in adult CHD cardiovascular morbidity



Serious alert!

- Adults with CHD: 51% smokers, 30% obese, 69% hypertension, 41% hyperlipidemia, and 7% diabetes mellitus
- High risk for heart failure (HR=13.0)
- High risk for acute coronary syndrome (HR=2.0)

Saha et al. *Circ* 2019

Solution: cardiovascular rehabilitation in youth with CHD as a preventive action

Main goals adapted from adult heart failure cardiovascular rehabilitation:

1. Physical activity training
2. Treatment optimization
3. Patient education

- Class I, level of evidence A in adult heart failure
- ↗ level of evidence in congenital cardiology
- Safe in patients with CHD

Ponikowski et al *EHJ* 2016
Yance et al. *Circ* 2017
Amedro et al. *Press Med* 2017

The QUALIREHAB trial

Main inclusion criteria

- 13-25 year old CHD patients
- VO_{2max} <80% and/or VAT <55%

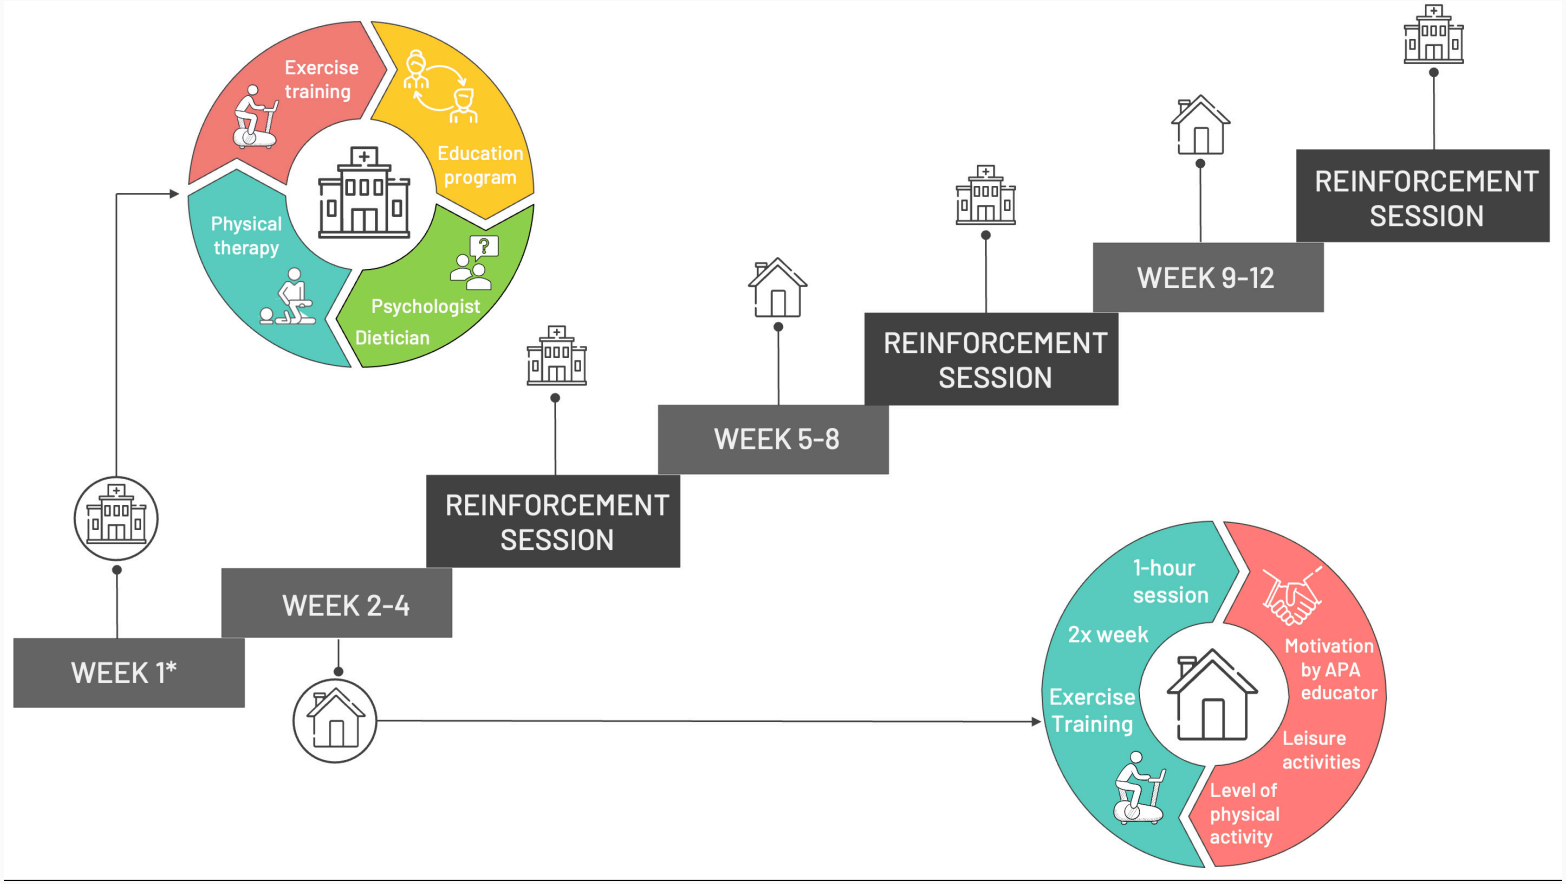
12-month follow-up

Rehabilitation center

12-week rehabilitation program

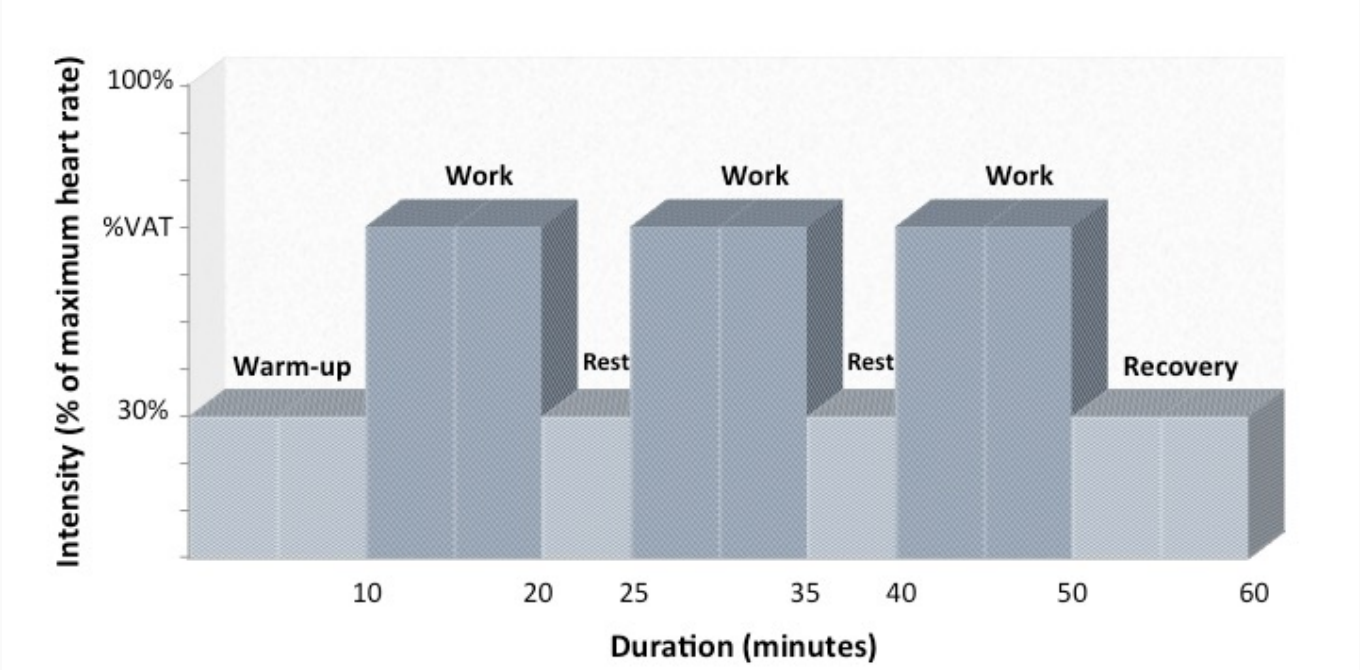
Home

The QUALIREHAB home-based & centre-based program



Interval training exercise at VAT level

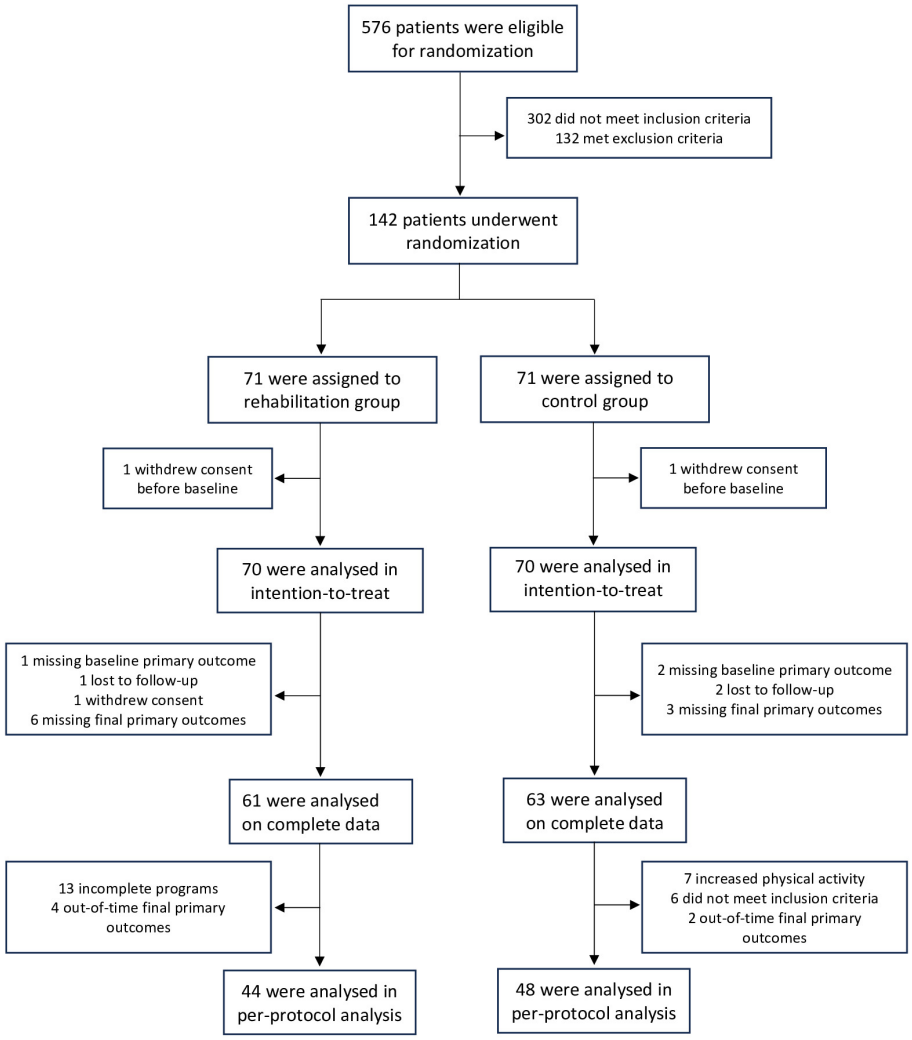
Moderate intensity (60% to 80 % VO_{2max})



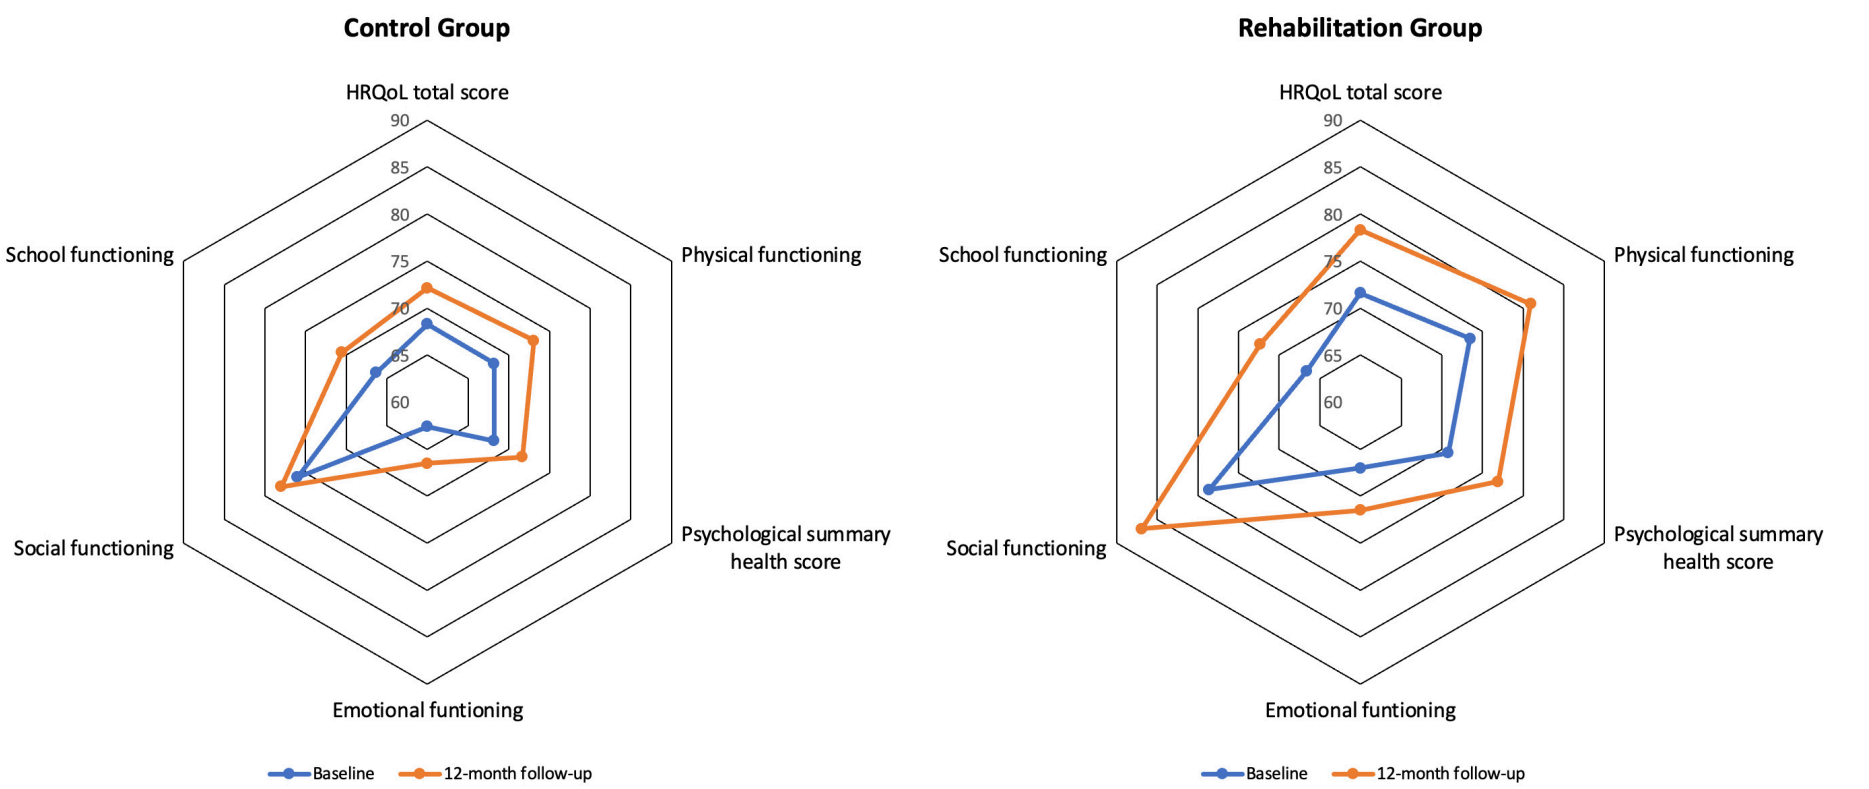
Amedro et al. *Perf Ped* 2021

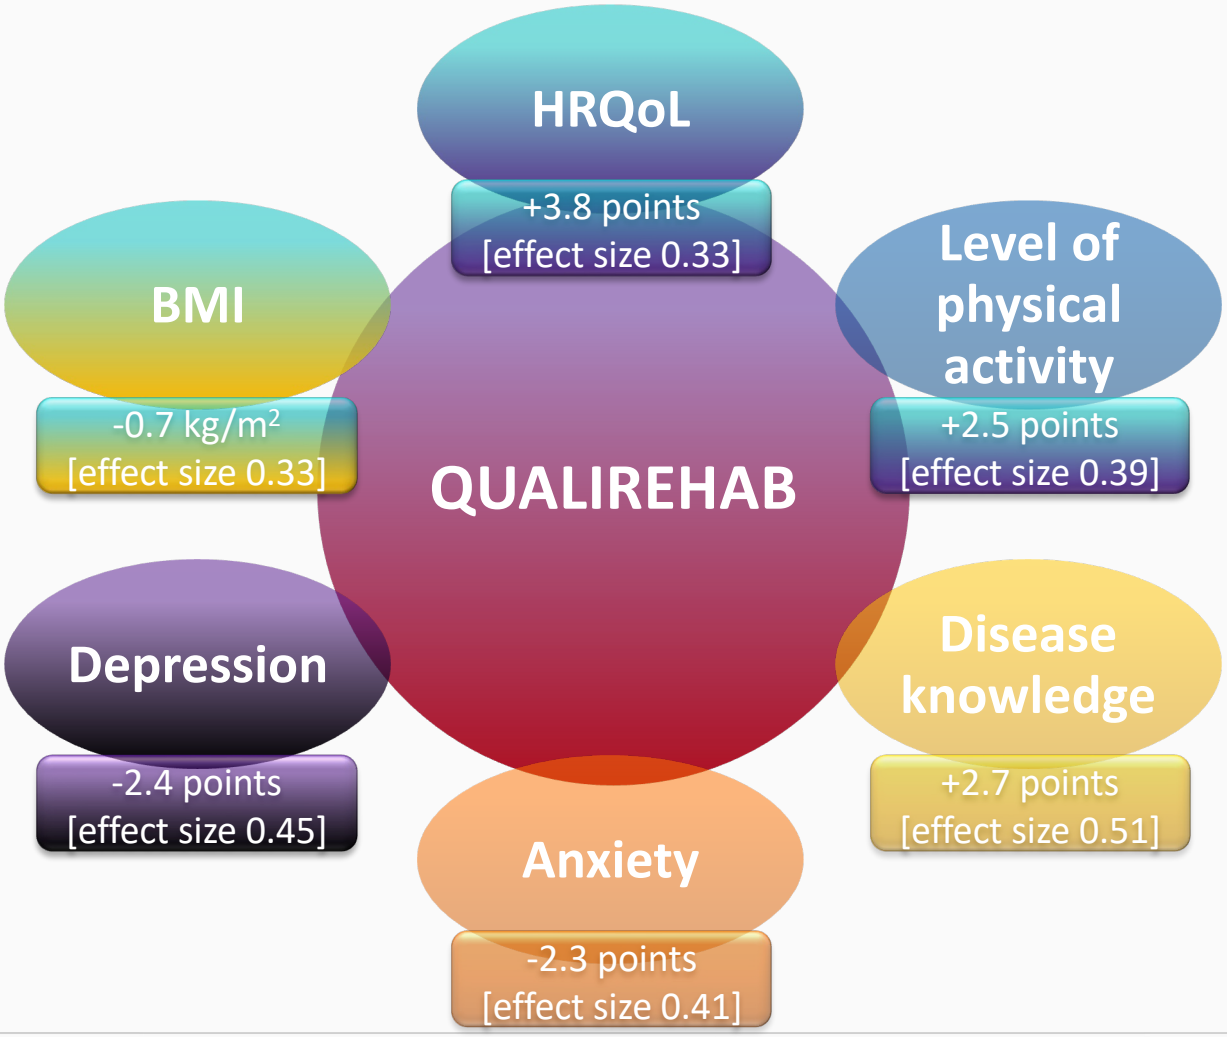
Population characteristics

- N = 142 participants
- Mean age 17.4 ± 3.4 years
- 52% female
- All types of CHD
- ≥ 1 cardiac surgery = 83%
- ≥ 1 intervention catheter = 44%
- Similar baseline group characteristics



Positive change in the primary outcome: HRQoL total PedsQL™ score at 12 months





HRQoL

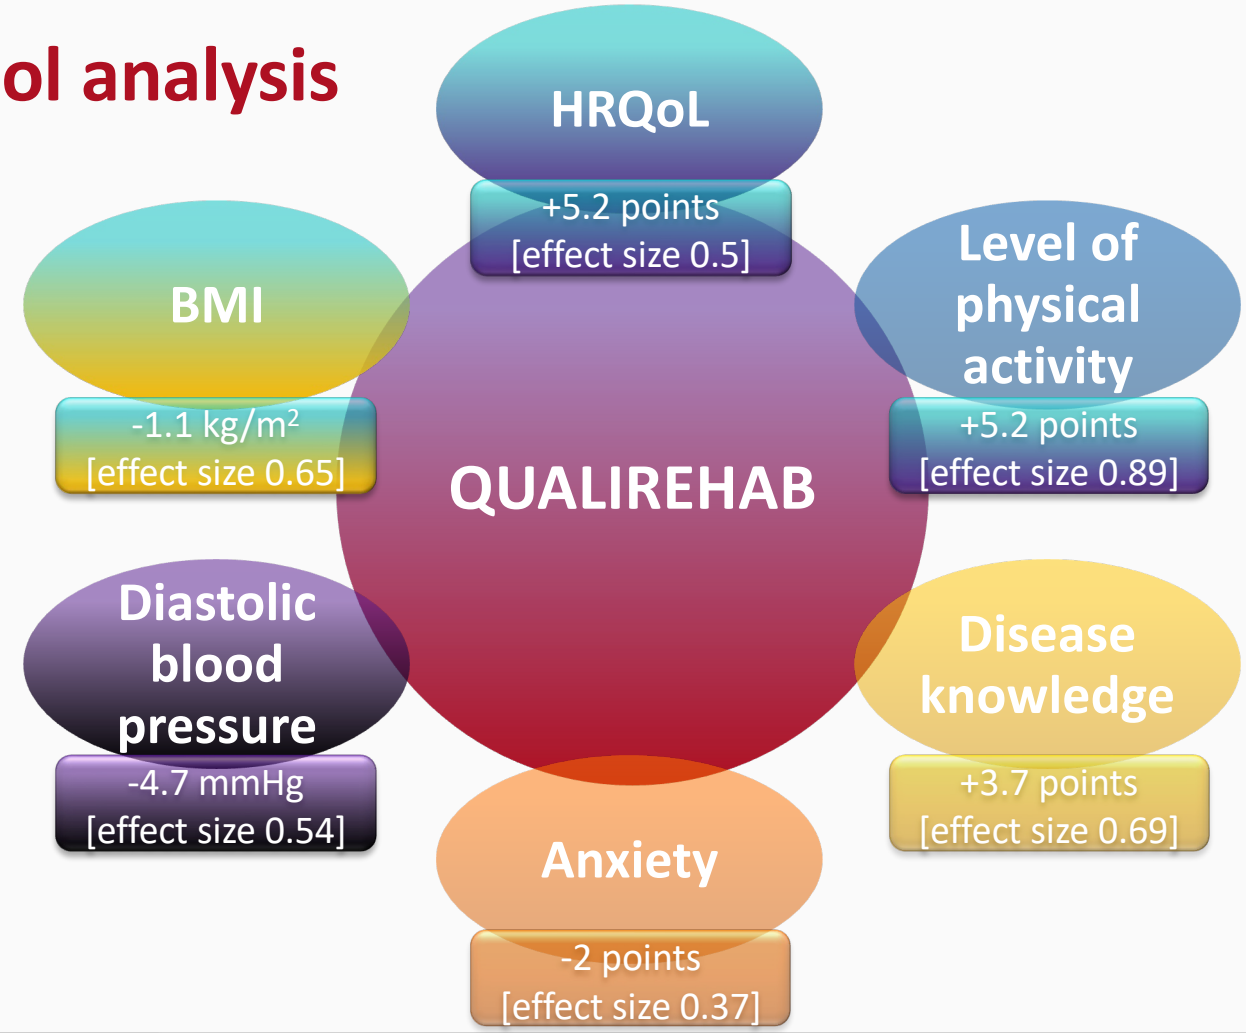
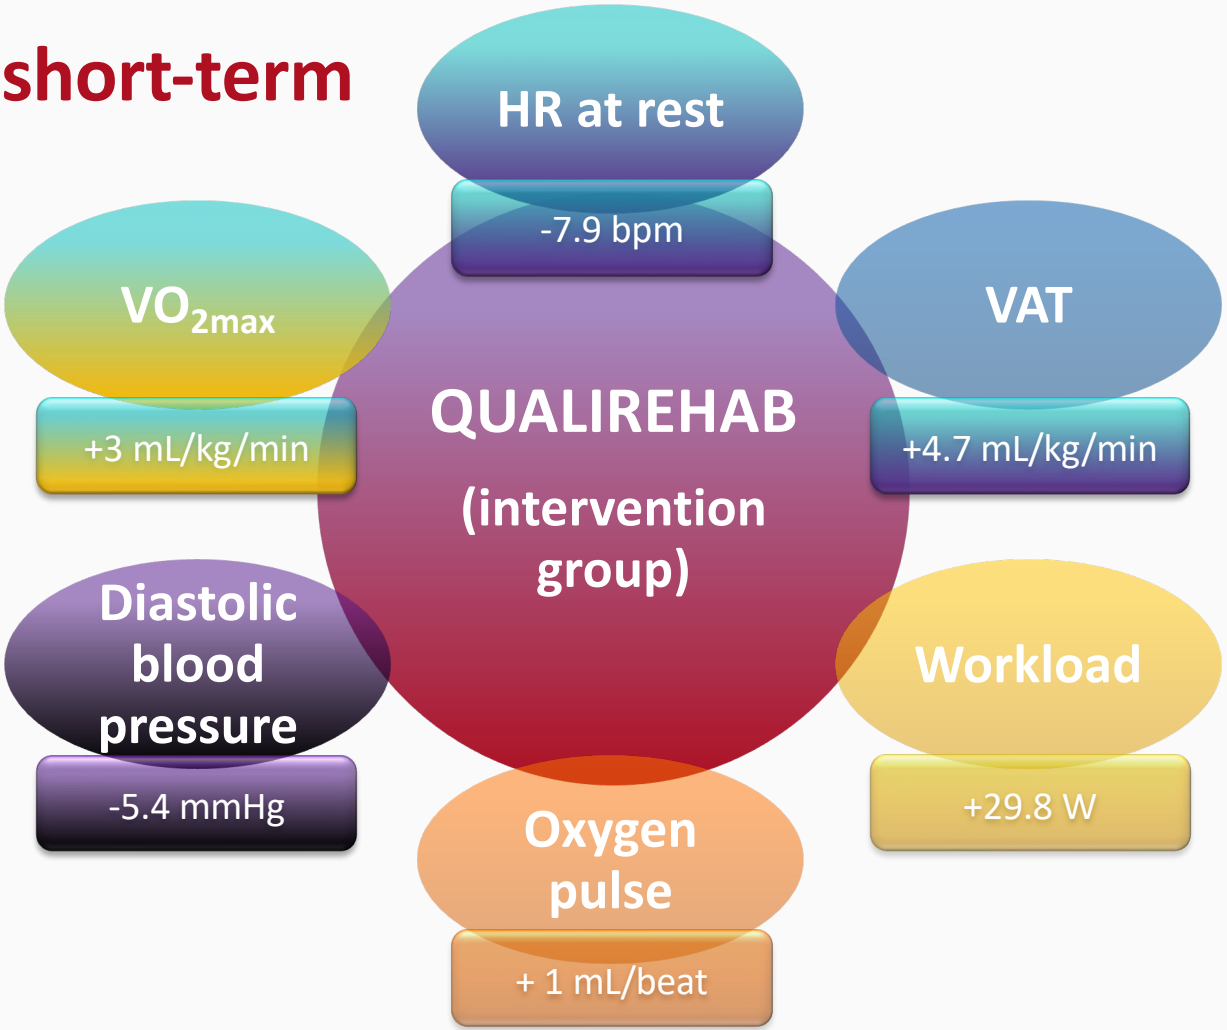
Per protocol analysis

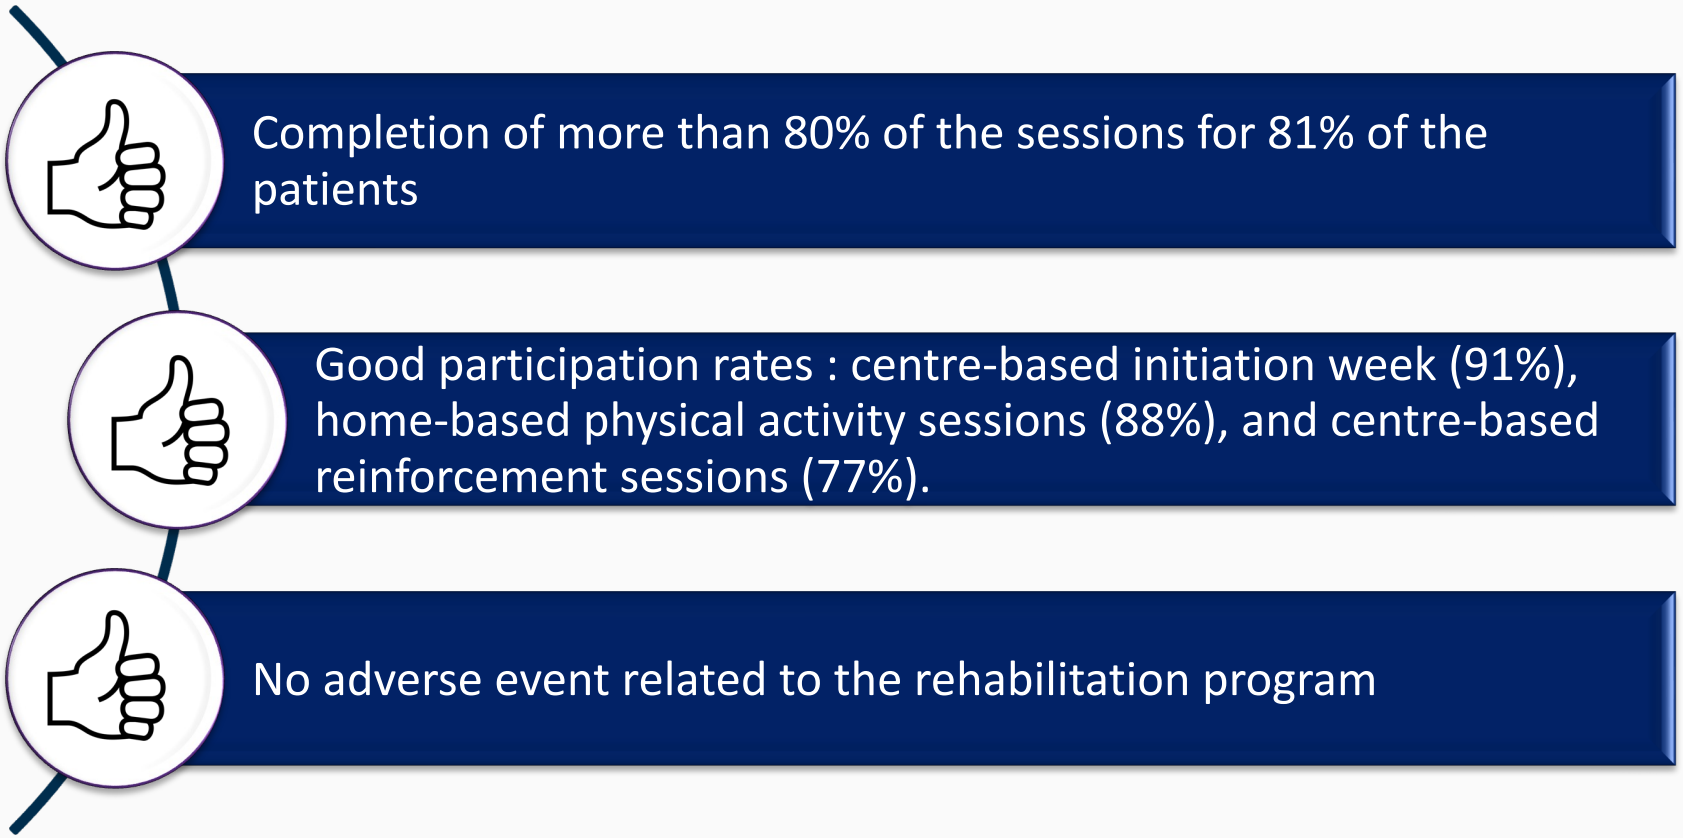


Significant short-term effects

12-week end of program assessment



Acceptability and safety of the intervention



Conclusions

- The QUALIREHAB **early hybrid cardiac rehabilitation program** opens the field to implement **prevention programs** in the usual care of young patients with CHD
- Applicable to other paediatric diseases with adult cardiovascular risk (childhood cancer)
- Main limit: VO_{2max} increased at week 12 but not at 12-month follow-up
- Future programs could combine high-intensity exercise, exercise progress monitoring, various patterns of training (i.e., exergame), and **post-rehabilitation support**.

The RATE-AF trial

UNIVERSITY OF BIRMINGHAM | INSTITUTE OF CARDIOVASCULAR SCIENCES

(1) Is digoxin inferior to beta-blockers for AF rate control?
(2) Can wearables account for individual physical activity?
(3) Can wearable data predict clinical progress?

RATE AF

Embedded within a clinical trial

Permanent atrial fibrillation in need of heart rate control with symptoms of heart failure

RANDOMISED

Low-dose digoxin (62.5-250 mcg/daily)

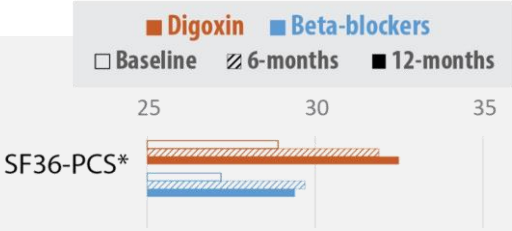
Beta-blockers (Bisoprolol 1.25-10 mg/daily)

160 patients randomised

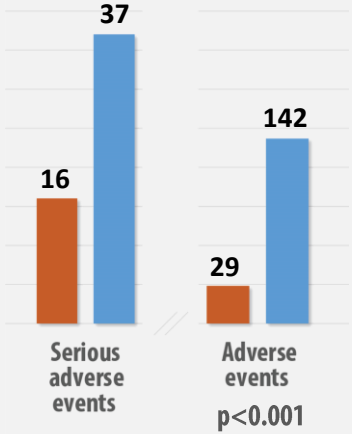
Average age 76

46% women

Symptoms: Moderate Severe



Significantly improved NYHA/mEHRA and NTpro-BNP with digoxin (p<0.01)



BMJ Open 2017;7:e015099

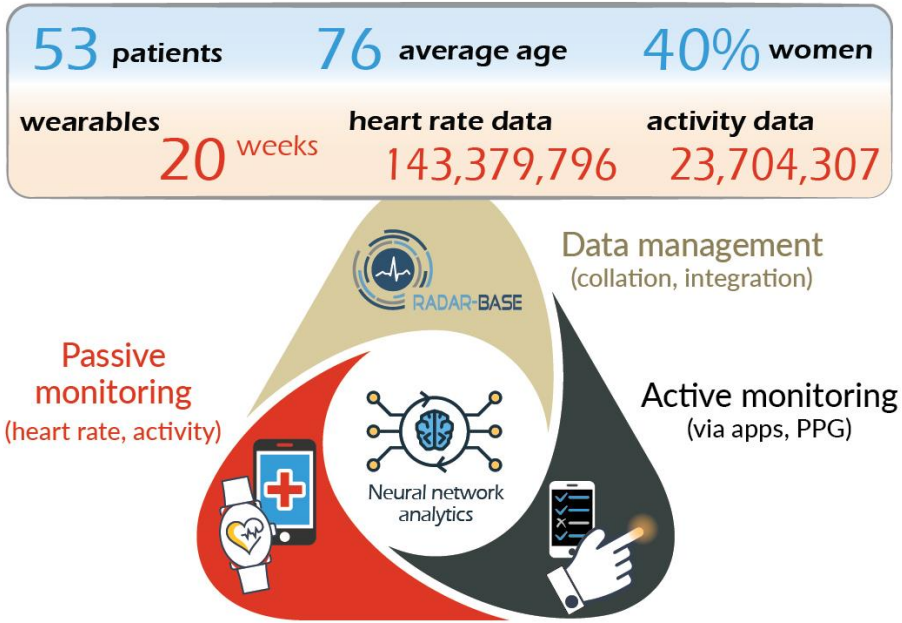
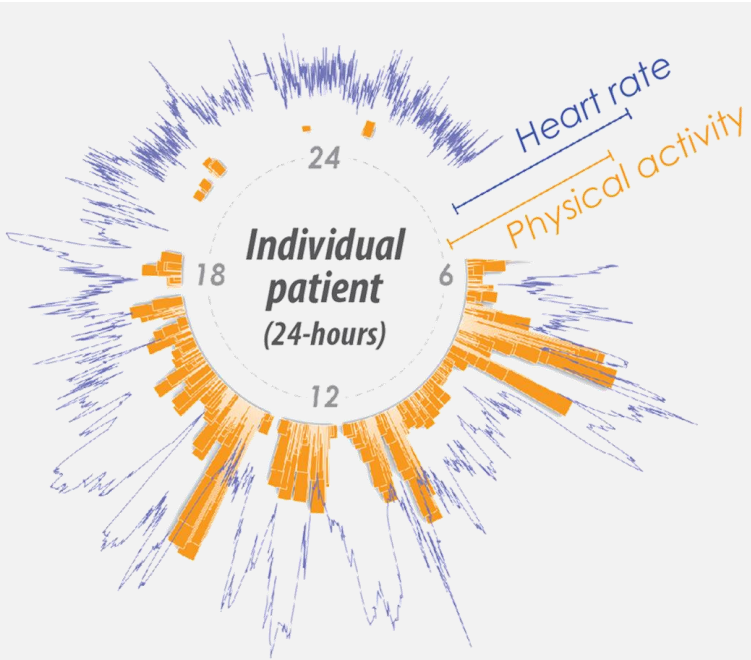
Approach

RATE AF

53 patients | 76 average age | 40% women

wearables: 20 weeks | heart rate data: 143,379,796 | activity data: 23,704,307



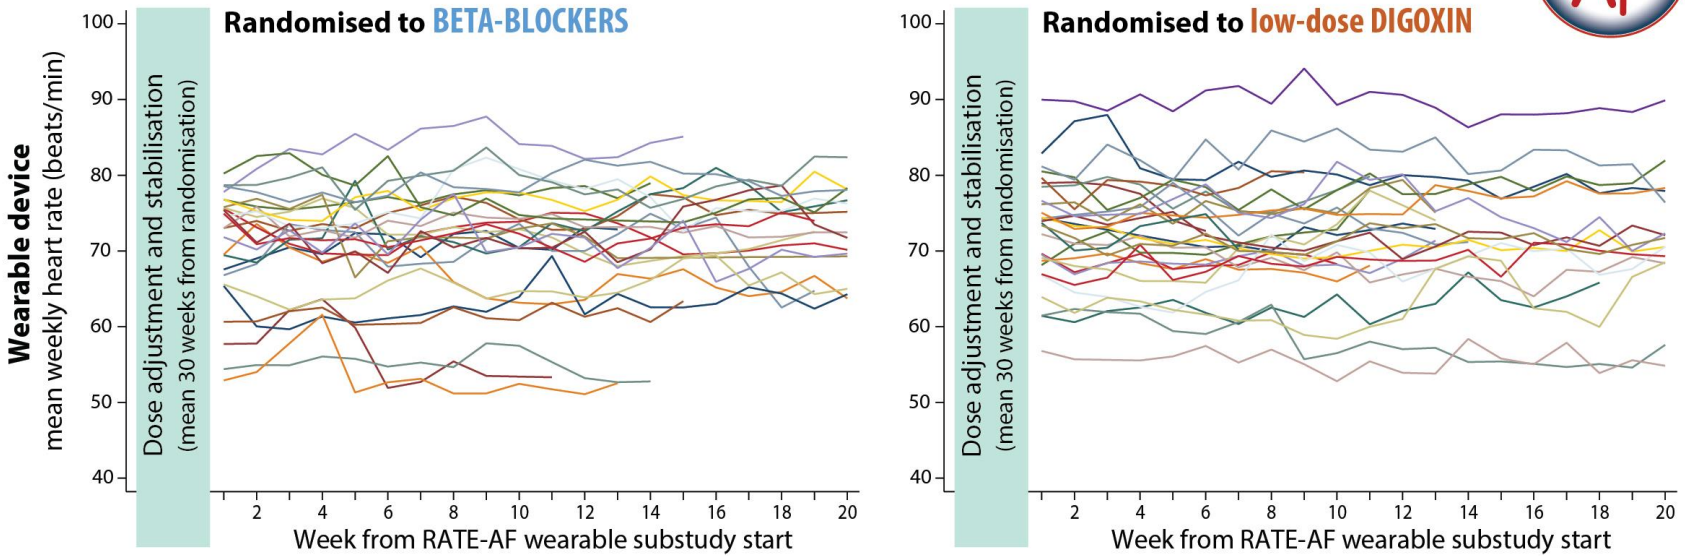


Mean number of heart rate data points per patient = **2.7 million** over a 20-week period

(1) Digoxin vs beta-blockers for heart rate control

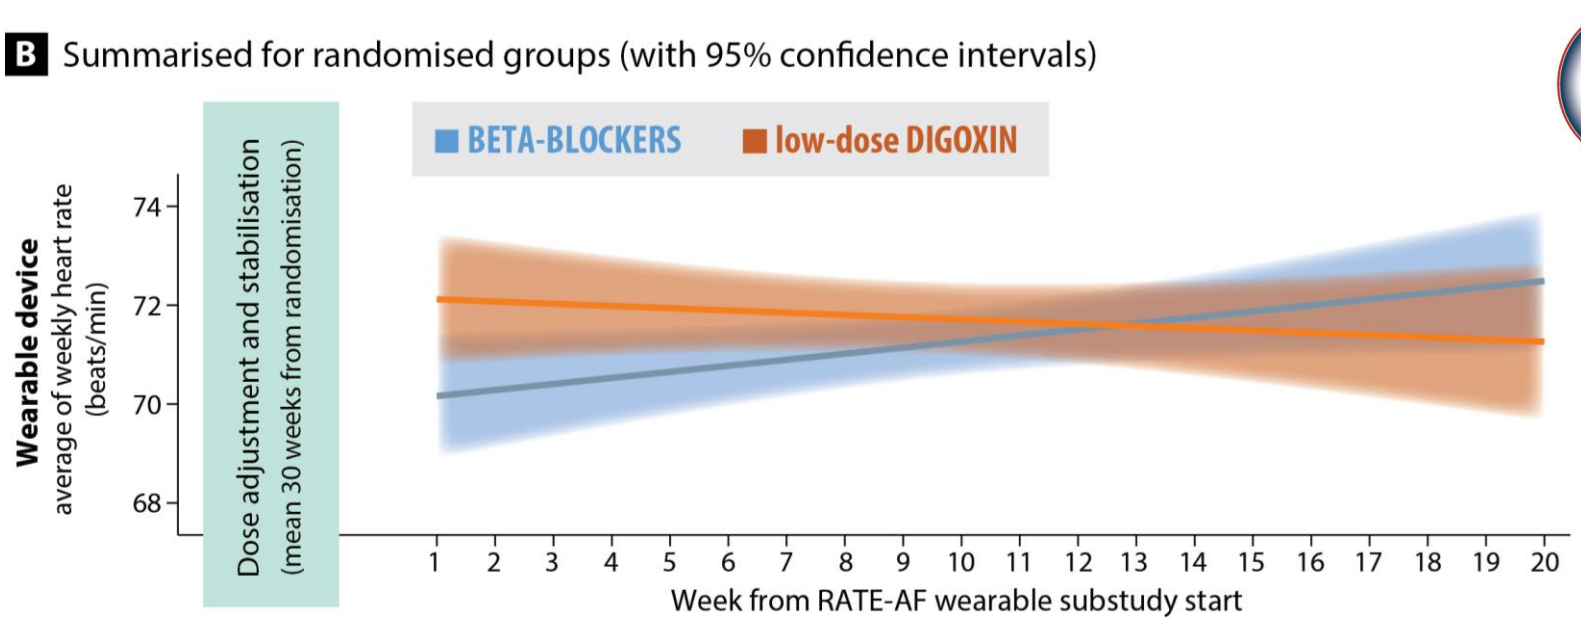
UNIVERSITY OF BIRMINGHAM | INSTITUTE OF CARDIOVASCULAR SCIENCES

A Trajectory for individual patients



(1) Digoxin vs beta-blockers for heart rate control (cont.)

UNIVERSITY OF BIRMINGHAM | INSTITUTE OF CARDIOVASCULAR SCIENCES



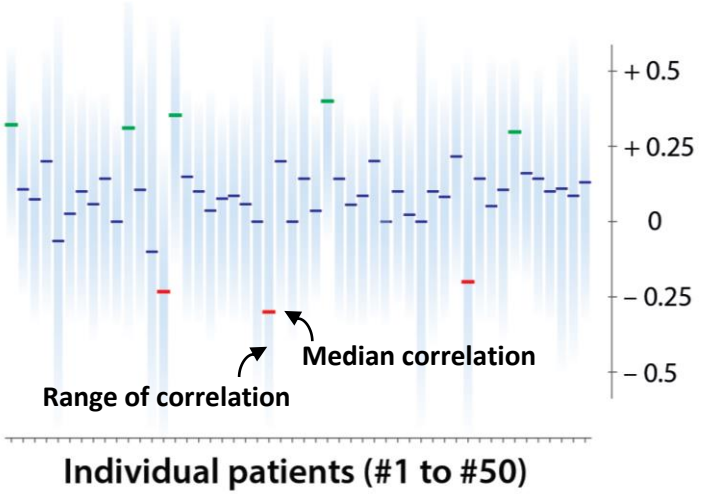
No difference in heart rate comparing digoxin and beta-blocker therapy using the wearable sensors:

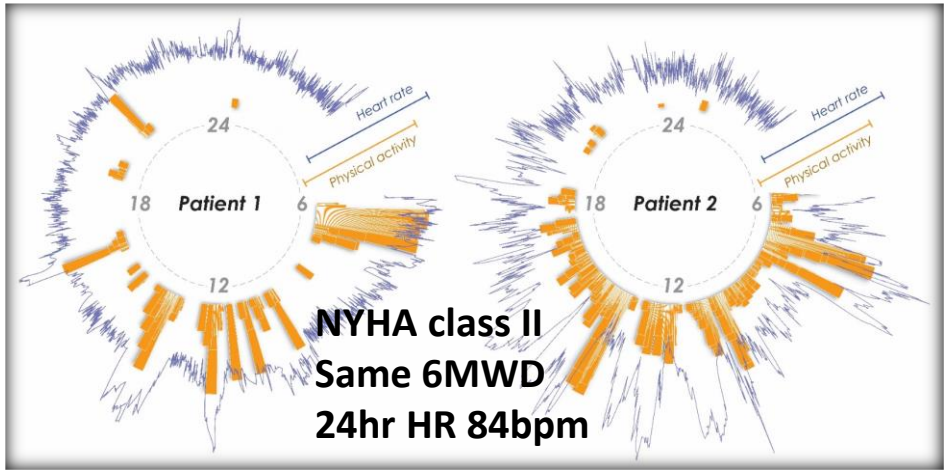
- **Unadjusted regression coefficient: 1.22 (95% CI -2.82 to 5.27; p=0.55)**
- **Adjusted for age, gender, diagnosis of heart failure and NT-proBNP: 0.66 (95% CI -3.45 to 4.77; p=0.75)**

(2) Accounting for physical activity

RATE AF

Correlation between heart rate and physical activity in rate-controlled patients with AF





No difference in heart rate comparing digoxin and beta-blocker therapy using the wearable sensors:

- **No difference after accounting for physical activity (p=0.74)**
- **No difference in any activity ranges:**
  - **<15,000 steps/week; p=0.48**
  - **15-30,000 steps/week; p=0.47**
  - **≥30,000 steps/week; p=0.97**

(3) Prediction of clinical progress

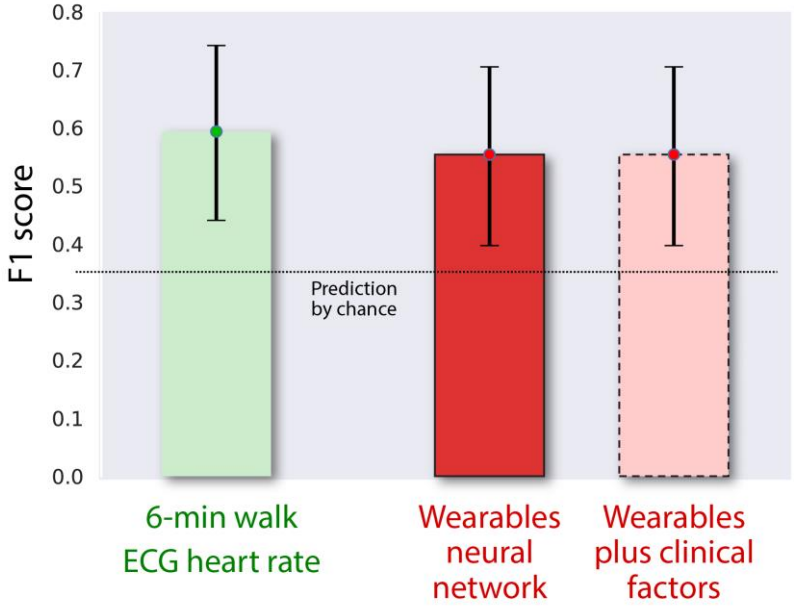
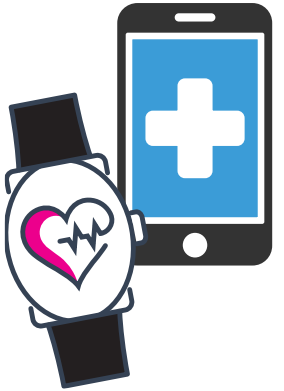
(average of 5 months later)



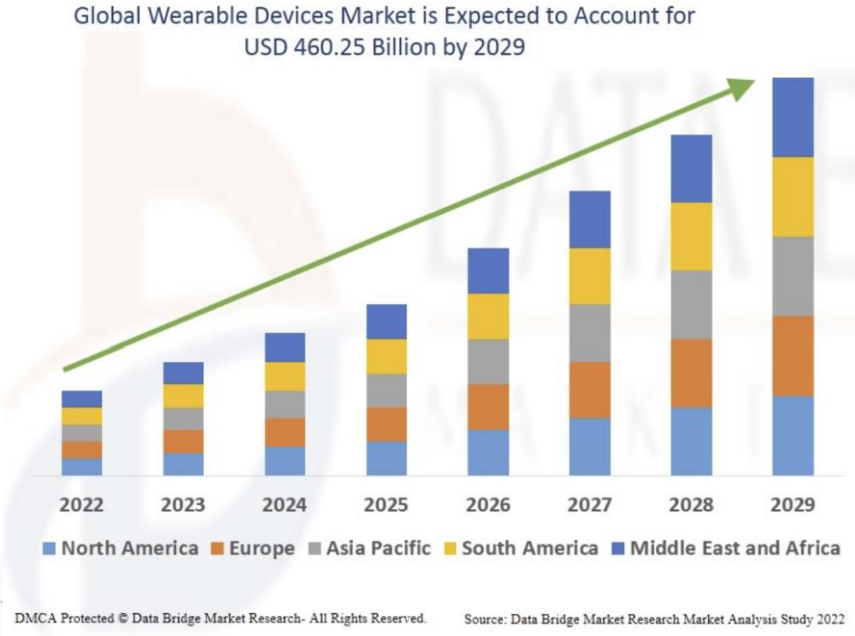


p=0.72

Summary, opportunities & limitations

- Consumer wearable devices are an exciting opportunity to gain information on dynamic physiological parameters
- Noisy and missing data are frequent, and required a novel neural network approach to avoid over-estimating the value of wearable data

- Digoxin and beta-blockers have equivalent effects on non-acute heart rate control in patients with AF, regardless of physical activity
- Dispels the preconception that digoxin is of limited use in highly-active patients



Post-procedural anticoagulation after primary percutaneous coronary intervention for ST-segment elevation myocardial infarction: a multicentre, randomised, double-blind trial

* Each center will use only one anticoagulant in all patients randomized at this center

Yan Y. et al. Am Heart J 2020;227:19-30; RIGHT ClinicalTrials.gov number, NCT 03664180

Study Endpoints

RIGHT

- **Primary efficacy endpoint**

  Composite of all-cause death, non-fatal myocardial infarction, non-fatal stroke, stent thrombosis (definite) or urgent revascularization (of any vessel) at 30 days

- **Primary safety endpoint**

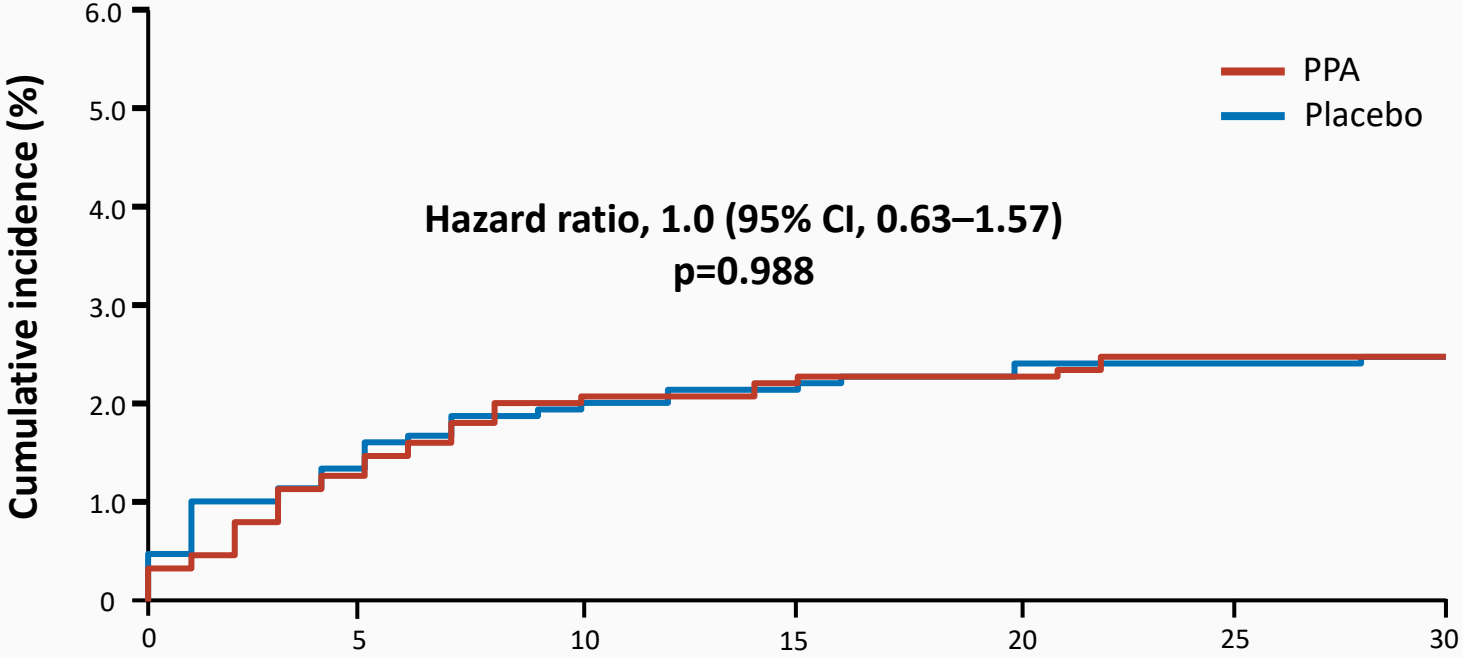
  Major bleeding (BARC definition type 3 to 5) at 30 days

Key Baseline Characteristics

Variables	PPA (n=1494)	Placebo (n=1495)
Age, years; mean (SD)	60.7 (12.4)	61.1 (12.3)
Male sex	1195/1494 (80.0)	1175/1495 (78.6)
Current smoking	763/1494 (51.1)	712/1495 (47.6)
Hypertension	830/1494 (55.6)	800/1495 (53.5)
Diabetes	359/1494 (24.0)	372/1495 (24.9)
Dyslipidaemia	637/1494 (42.6)	623/1495 (41.7)
Prior myocardial infarction	107/1494 (7.2)	92/1495 (6.2)
Chronic kidney disease	30/1494 (2.0)	28/1495 (1.9)
Anterior STEMI	640/1494 (42.8)	658/1495 (44.0)
Door-to-balloon time, minutes; median (IQR)	74 (55, 99)	75 (53, 103)
Aspirin before angiography	1467/1494 (98.2)	1458/1495 (97.5)
$P2Y_{12}$ inhibitor loading before angiography	1425/1494 (95.4)	1407/1495 (94.1)

Primary Efficacy Endpoint

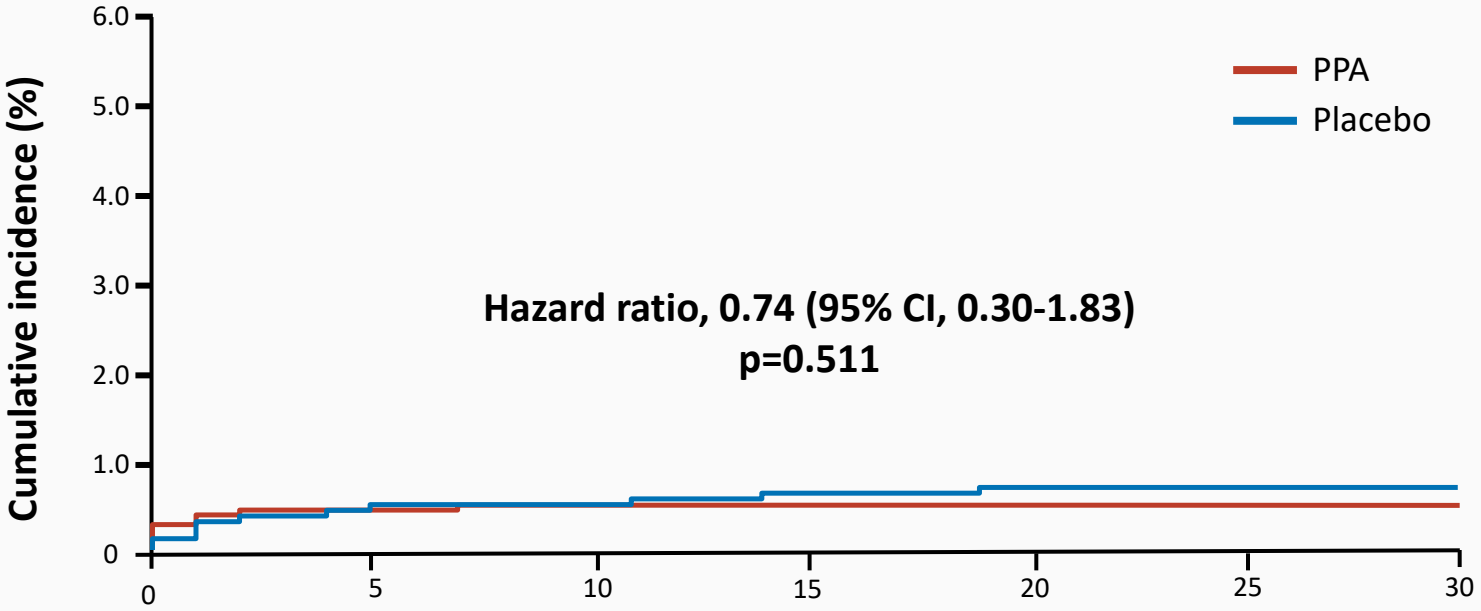
RIGHT



No. at risk							
Placebo	1495	1475	1466	1463	1461	1459	1458
PPA	1494	1475	1464	1461	1460	1457	1457

Primary efficacy endpoint: Death, MI, stroke, stent thrombosis or urgent revascularization at 30 days

Primary Safety Endpoint



No. at risk							
Placebo	1488	1470	1462	1458	1457	1456	1456
PPA	1468	1448	1440	1438	1437	1435	1435

Primary safety endpoint: Major bleeding (BARC 3 to 5) at 30 days

Secondary Exploratory Findings

A **Primary efficacy outcome in three anticoagulation regimen groups**

Subgroup	PPA	Placebo	Hazard ratio (95%CI)	*p for interaction 0·015*
	no./total no. (%)			
Enoxaparin	10/474 (2·1)	21/471 (4.5)		0·46 (0·22-0·98)
UFH	11/510 (2·2)	3/512 (0·6)		3·71 (1·03-13·28)
Bivalirudin	16/510 (3·1)	13/512 (2·5)		1·24 (0·60-2·59)

B **Primary safety outcome in three anticoagulation regimen groups**

Subgroup	PPA	Placebo	Hazard ratio (95%CI)	*p for interaction 0·679*
	no./total no. (%)			
Enoxaparin	3/466 (0·6)	5/470 (1·1)		0·60 (0·14-2·52)
UFH	2/503 (0·4)	4/508 (0·8)		0·50 (0·09-2·75)
Bivalirudin	3/499 (0·6)	2/510 (0·4)		1·54 (0·26-9·24)

Conclusion & Clinical Implications

RIGHT

- Routine PPA using low-dose anticoagulation after primary PCI is safe but does not improve ischaemic outcome at 30 days
- Our data suggest that the three anticoagulants may not be equivalent in the prevention of 30-day ischaemic events but this finding deserves confirmation in future studies

Outcomes of mitral transcatheter edge to edge repair versus isolated mitral surgery for the treatment of severe mitral regurgitation:

data from a nationwide analysis.

Pierre Deharo, MD, PhD, FESC; on behalf of all co authors

CHU la Timone, Marseille, France

25 August 2023

Background

Mitral regurgitation (MR) is the more prevalent valvular disease in western countries

In all registries, MR is undertreated and/or at a late stage

MR treatment is associated with poor prognosis (in older patients)

When considering MR, 1ary and 2ary MR could be differentiated

Background

Treatment of MR is indicated by the severity of MR

Isolated mitral surgery (repair/replace) has been the only curative treatment for severe MR

From 2011, transcatheter edge-to-edge repair (TEER) has offered an alternative to surgery for the treatment of severe MR

Objective

To compare long-term outcomes of TEER vs. isolated mitral valve surgery at a nation wide level in France

To compare long-term outcomes of TEER vs. isolated mitral valve repair at a nation wide level in France

To evaluate long-term outcomes of TEER vs. isolated mitral valve surgery in *1ary and 2ary MR* at a nation wide level in France

Methodology

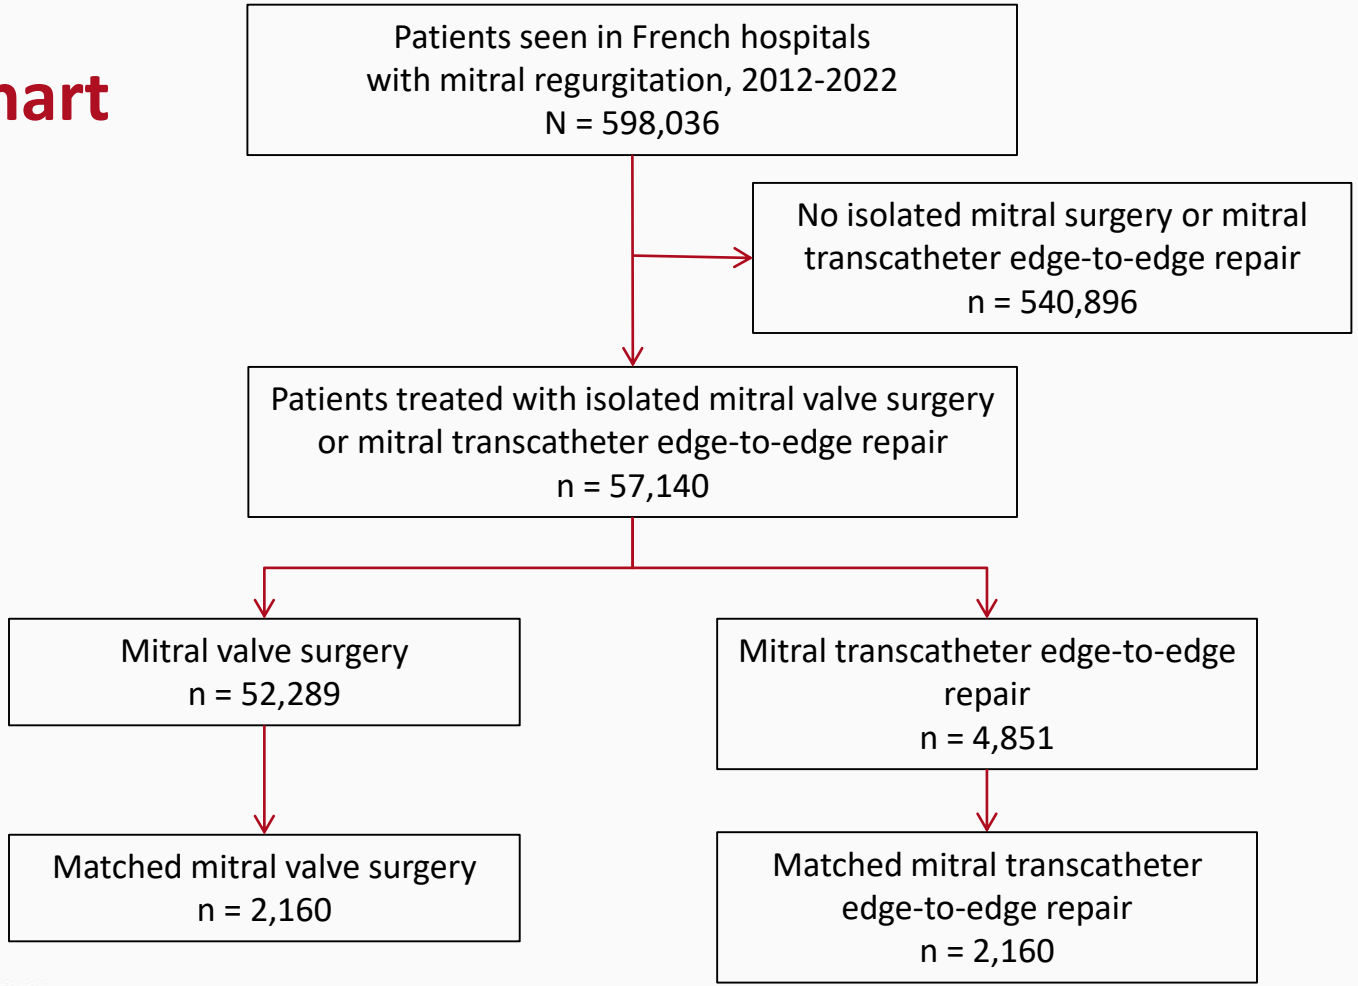
Nationwide analysis

From PMSI database including all patients admitted for severe MR in France from January 2012 to June 2022

Identification and distinction of procedures based on their CCAM codes

Distinction between 1ary and 2ary MR based on codes

Flow chart



FUP 1.0 (± 1.2) year

Baseline characteristics (unmatched)

Interaction between subgroups and cardiovascular mortality

Cardiovascular death	Surgery (n=2160)		TEER (n=2160)					
	Number of patients	Number of events	Number of patients	Number of events	Hazard ratio (95% CI)	p value	HR for interaction	p value for interaction
Age <75 yrs	744	51	744	53	0.973 (0.662-1.430)	0.89		
Age ≥75 yrs	1416	119	1416	119	0.608 (0.484-0.764)	<0.0001	**0.611** (0.391-0.955)	**0.03**
EuroSCORE II <4	1274	66	1290	74	1.078 (0.773-1.502)	0.66		
EuroSCORE II ≥4	886	181	870	98	0.539 (0.421-0.689)	<0.0001	**0.487** (0.322-0.736)	**0.0006**

Outcomes (3)

When comparing long-term outcomes of TEER vs. isolated mitral valve repair, cardiovascular death was lower in TEER group versus surgery (IRR 0.698, 0.561-0.869, p 0.001).

When differentiating 1ary versus 2ary MR, cardiovascular death was lower in TEER group versus surgery when treating 2ary MR (IRR 0.664, 0.522-0.846, p 0.001).

In 1ary MR the differences did not reach significance (p 0.08).

Conclusion (1)

Largest propensity matched comparison of mitral TEER versus isolated mitral valve surgery for patients with severe MR

During follow-up we observed that mitral TEER was associated with lower rates of cardiovascular death, pulmonary edema, atrial fibrillation, pacemaker implantation, stroke, major bleeding and endocarditis in matched cohort

Conclusion (2)

We showed a significant interaction between age > 75 years and Euroscore ≥ 4 and reduced cardiovascular and all-cause mortality after TEER versus surgery.

Same differences were reported when including only isolated mitral valve repair (excluding replacement) versus mitral TEER.

In 2ary MR, TEER was associated with lower incidences of cardiovascular death than isolated surgery.

COP-AF TRIAL

Colchicine For the Prevention of Peri-Operative Atrial Fibrillation After Major Thoracic Surgery

International, Prospective, Randomized Trial

OBJECTIVE: To evaluate the effect of colchicine on the incidence of perioperative atrial fibrillation (AFib) and myocardial injury after noncardiac thoracic surgery (MINS)

3,209

(1,608 COLCHICINE, 1,601 PLACEBO) PATIENTS

INCLUSION CRITERIA:

- Patients age ≥ 55 undergoing major noncardiac thoracic surgery under general anesthesia without a history of AFib or contraindication to colchicine use

1:1 RANDOMIZATION TO COLCHICINE

VS.

PLACEBO

PRIMARY ENDPOINT

CO-PRIMARY OUTCOMES OF CLINICALLY IMPORTANT PERIOPERATIVE AFIB OR PROGNOSTICALLY IMPORTANT POSTOPERATIVE ISCHEMIC TROPONIN ELEVATION WITHIN 14 DAYS OF SURGERY

SECONDARY ENDPOINTS

COMPOSITE OF ALL-CAUSE MORTALITY, NONFATAL MINS, OR NONFATAL STROKE

COMPOSITE OF ALL-CAUSE MORTALITY, NONFATAL MI, OR NONFATAL STROKE

MINS NOT FULFILLING THE STANDARD MYOCARDIAL INFARCTION DEFINITION

MYOCARDIAL INFARCTION

CONCLUSION

Colchicine did not significantly reduce the incidence of clinically significant perioperative AFib or MINS following major noncardiac thoracic surgery

Conen D, Devereaux PJ, Healey JS, et al. Colchicine for the Prevention of Peri-Operative Atrial Fibrillation After Major Thoracic Surgery. *Lancet* 2023;Aug 25:[Epublished].

SYRINGE

PRIMARY ENDPOINT

THE PRIMARY OUTCOME OF DIURETIC EFFICIENCY (CUMULATIVE WEIGHT CHANGE/CUMULATIVE IV AND ORAL LOOP DIURETIC) FAVORED DAPAGLIFLOZIN (OR 0.65, 95% CI 0.41-1.01, P=0.06).

SECONDARY ENDPOINTS

EARLY DAPAGALIFLOZIN SIGNIFICANTLY IMPROVED NATURIESIS (P=0.025); TIME TO COMPLETING IV DIURETIC THERAPY (P=0.006); AND TIME TO HOSPITAL DISCHARGE (P=0.007). DAPAGLIFLOZIN WAS SAFE ACROSS ALL DIABETIC AND CARDIORENAL IN-HOSPITAL OUTCOMES.

CONCLUSION

Early initiation of dapagliflozin to facilitate decongestion and GDMT optimization is safe and improves diuretic efficiency in patients with ADHF.

Cox Z, et al.; Efficacy and Safety of Dapagliflozin in Acute Heart Failure (DICTATE-AHF; NCTO4298229); Presented at ESC Congress 2023, Amsterdam; Aug. 27, 2023

Sex Differences in FLAVOUR Trial

Sex Differences in Fractional Flow Reserve (FFR)- or Intravascular Ultrasound (IVUS)-Guided Percutaneous Coronary Intervention (PCI)

Multicenter, International, Open-Label, Noninferiority, Investigator-Initiated Randomized Trial

OBJECTIVE: Secondary analysis to identify sex differences in procedural characteristics, treatment and clinical outcomes according to the use of FFR or IVUS for PCI guidance.

1,619
PATIENTS

INCLUSION CRITERIA:
- Ischemic heart disease suspected
- Intermediate stenosis on angiography
- Target vessel 2.5 mm in diameter
- IVUS or FFR performed as assigned in original trial

WOMEN (482)

VS.

MEN (1,137)

PRIMARY ENDPOINT

COMPOSITE OF CARDIAC DEATH, TARGET VESSEL MI AND TARGET VESSEL REVASCULARIZATION AT 24 MONTHS WAS LOWER IN WOMEN THAN IN MEN (2.4% vs. 4.5%).

SECONDARY ENDPOINTS

WOMEN RECEIVED FEWER TOTAL INTERVENTIONS:

TOTAL: 40.8% PCI vs. 47.9% PCI

FFR GROUP: 25.0% vs. 36.8%

IVUS GROUP: 58.4% vs. 59.3%

CONCLUSION

In patients undergoing coronary angiography found to have intermediate stenosis, women had lower rates of target vessel failure than men despite undergoing fewer PCI.
